

15/03/2022

## UNIT-1

### Introduction

### Structure of Compiler

#### Translator:-

Translators convert high level language program to low level language programme (or) machine code.

The different translators are :-

(i) Compiler

(ii) Interpreter

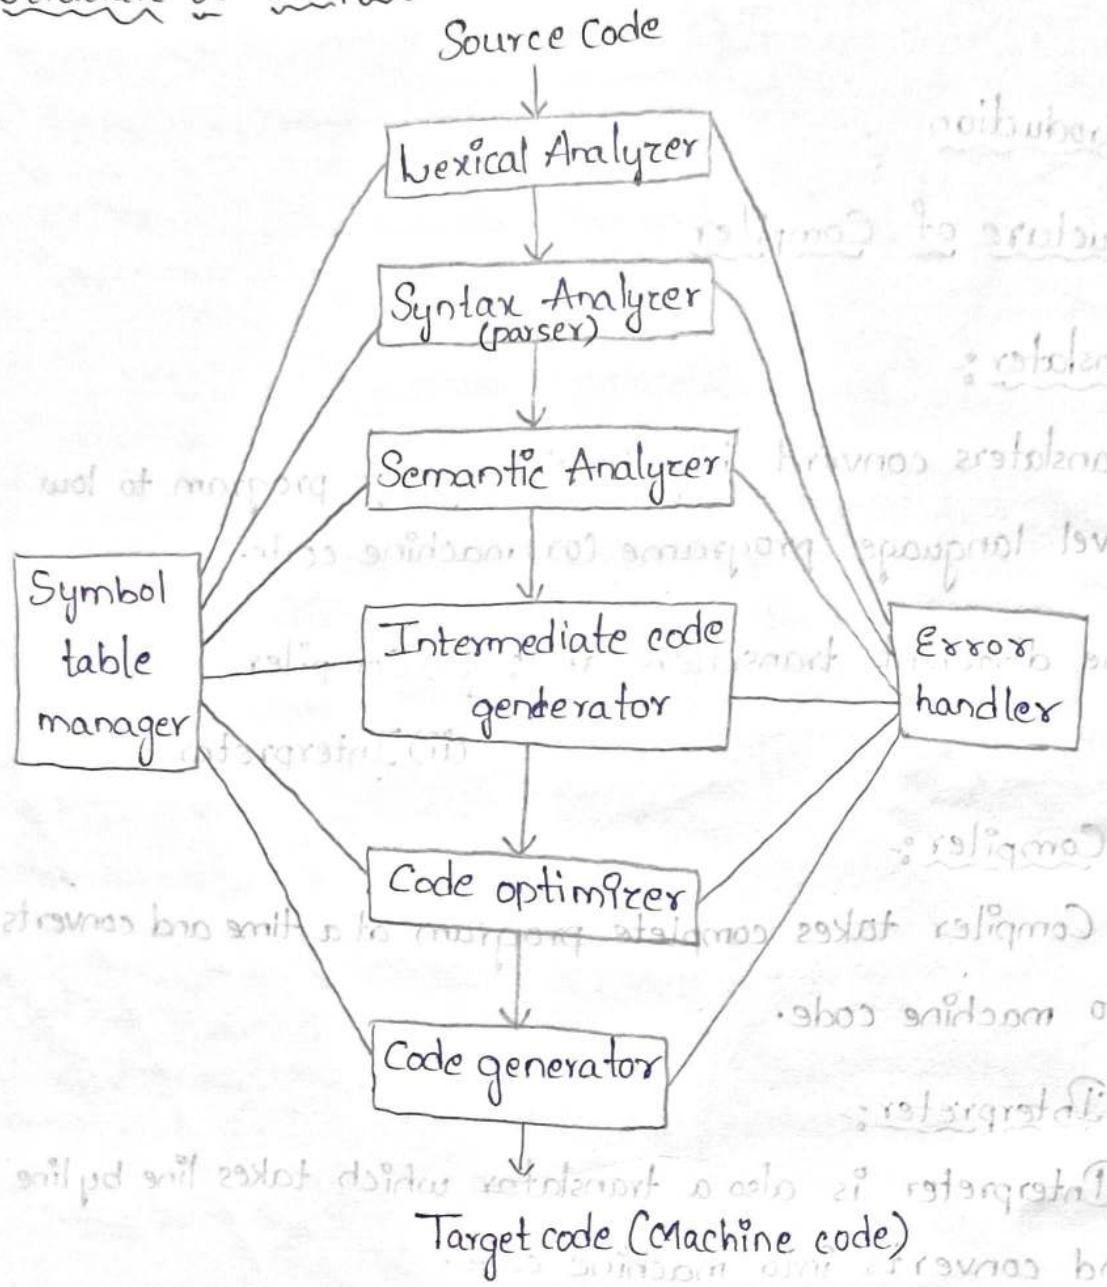

#### (i) Compiler:-

Compiler takes complete program at a time and converts into machine code.

#### (ii) Interpreter:-

Interpreter is also a translator which takes line by line and converts into machine code.

# Structure of Compiler (or) Phases of a Compiler

(i) Lexical Analyzer- It takes an instruction and divides it into small units known as lexemes (or) tokens.

Given

instruction  $c \rightarrow \text{Identifier}$

$c = a + b$   $= \rightarrow \text{assignment Operator}$

$a \rightarrow \text{Identifier}$

$+ \rightarrow \text{Addition operator}$

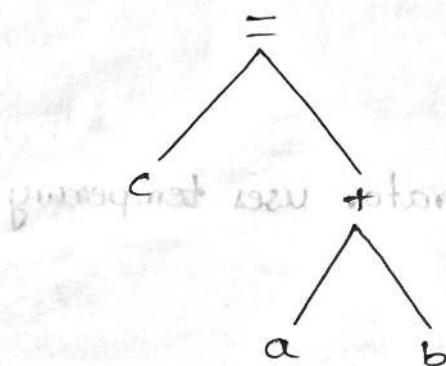

$b \rightarrow \text{Identifier}$

(ii) Syntax Analyzer :- Syntax analyzer is also known as Parser.

It takes the instruction and converts it into syntax tree or parse tree. With the help of this syntax tree errors can be identified.

Ex :- Given instruction  $c = a + b$

The syntax tree for the given statement is

(iii) Semantic Analyzer :-

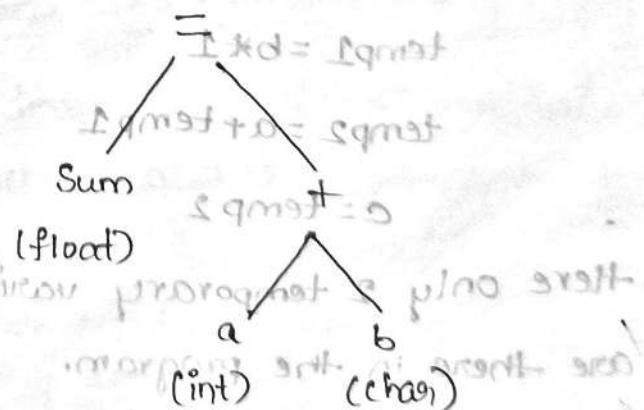

It scans the syntax tree and checks whether rules of a language is followed or not. That means, semantic analyzer checks the errors in the syntax trees. It also verifies the data types of identifiers.

Ex :-

Sum = a + b

Semantic Record

|       |     |
|-------|-----|
| float | sum |
| int   | q   |
| char  | b   |

There is an error in the syntax tree, because character integer cannot be added.

16/03/2022

(iv) Intermediate code generator :- It generates the code using temporary variables.

Ex:-

$$c = a + b * 1;$$

$$\text{temp1} = 1$$

$$\text{temp2} = b * \text{temp1}$$

$$\text{temp3} = a + \text{temp2}$$

$$c = \text{temp3}$$

Intermediate code generator uses temporary

(v) Code optimizer:-

Code optimizer tries to reduce temporary variables and number of lines in the intermediate code. By doing this execution performance can be increased and memory will also be saved.

Ex:-

$$c = a + b * 1;$$

The above intermediate code can be optimized as follows:-

$$\text{temp1} = b * 1$$

$$\text{temp2} = a + \text{temp1}$$

$$c = \text{temp2}$$

Here only 2 temporary variables are used, only 3 lines are there in the program.

(vi) Code generator :- Code generator takes the given instruction & converts into assembly code (or) Pneumatic code. After that, assembly code is converted into machine. This machine code is known as Target code.

Ex:-

$$C = a + b * 1$$

assembly code (Pneumatic code)

Mov R<sub>1</sub>, b

Machine code

Mul R<sub>1</sub>, #1

10110  
11110

Mov R<sub>2</sub>, a

00101

Add R<sub>2</sub>, R<sub>1</sub>

10111  
11011

STR C, R<sub>2</sub>

19/03/2022

### The science of Building a Compiler

A compiler must accept any length of source code which is very small or large and transformation should be performed without changing the meaning of the program.

#### Modeling in Compiler design and Implementation :-

→ Design :- The compilers are design based on mathematical models like finite state machines and Regular expression.

→ These mathematical models are used to identify

### 3) Context free grammar:-

The context free grammar which is used to describe syntactical errors in given expression.

### 4) Science of Tree:-

The science of tree which is used in compiler used to detect errors in given expression.

### Science of code optimization

1) Optimization:- The word optimization means increasing the efficiency and performance.

2) Tries to reduce unwanted code:- The science of code optimization tries to reduce unwanted code in given program, improves expression speed.

→ Data abstraction & inheritance concepts can be used to optimize the code in a program.

22/02/2022

### Programming Language Basics: (evolution of computers, History of Computers)

The history of programming languages start from mechanical computers to modern tools for software development.

In early 1950's, assembly language is used. Here programming is done using mnemonics codes like add, sub, mul etc.,

- In later half of 1950's, development of fortran is done for writing engineering & scientific application, and cobal was developed for writing business oriented programming.
- After 1950's, many more languages were created with innovative features which helps easy programming, more natural & more robust.

### Classification of Languages by generation:

- In first generation, machine language is used for writing program.
- In 2<sup>nd</sup> generation, assembly language is used for writing program.
- In 3<sup>rd</sup> generation, high level languages like fortran, cobal, c, c++ were developed for writing programs.
- In 4<sup>th</sup> generation, languages design for specific applications like dBASE, foxpro, sql. All these languages are used to store data in database.
- In 5<sup>th</sup> generation, logical constrained based languages like prolog and OPS 5 (Official Production System Version 5). were developed which were used in expert system.

## Object Oriented Languages

Object Oriented Languages support object oriented programming. This programming consists of objects which communicate with each other through message passing technique.

## Scripting Languages

Scripting languages are developed for writing web applications.

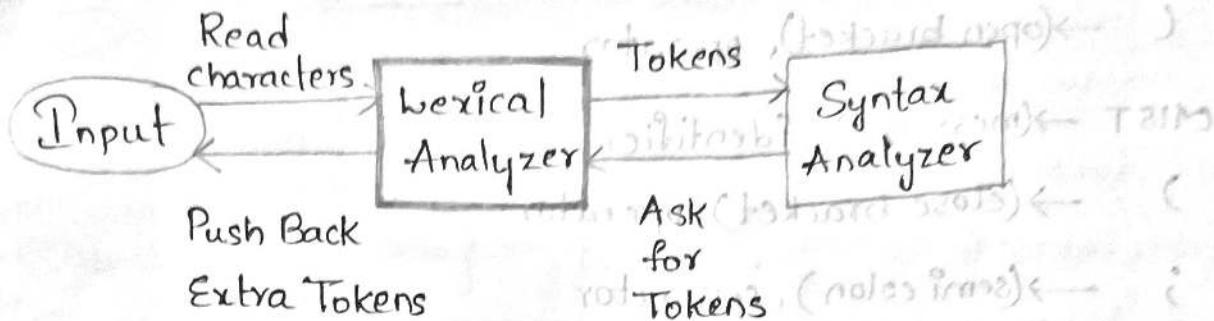

Ex:- Java script, perl, PHP, ruby, TLL.

13/03/2022

## Part - 2

### Lexical Analysis

### The Role of Lexical Analyzer

lexical analysis is the first phase of the compiler. It is also known as Scanner. It reads characters from the input statement and forms a meaningful tokens (or) lexemes and these tokens are given to Syntax analyzer.

### function of Lexical Analyzer

- i) Divide the program into valid tokens.
- ii) Remove white space characters.
- iii) Remove comments.
- iv) It also provides help in generating error messages by providing row number and column number.

Ex-1:-

- Suppose we pass a statement  $a = b + c$ , it will generate token sequence as given below:

$a \rightarrow$  identifier

$= \rightarrow$  assignment operator

$b \rightarrow$  identifier

$+ \rightarrow$  add operator

$c \rightarrow$  identifier

The above data is given to syntax analyzer.

Ex-2

printf("MIST");

printf → keyword

( →(open bracket), operator

MIST →(message), identifier

) →(close bracket), operator

; →(semicolon), separator

24/03/2022

## Input Buffering

Generally, lexical analyzer reads character by character of the given program & produces stream of tokens.

To read characters & produce token, two pointers are required they are

(i) Lexim begin pointer

(ii) Forward pointer

Generally, Lbp is placed at starting point of the token while reading the characters.

FP reads character by character until it sees white space or comma, or semicolon or EOF. It is considered as end of token.

End Of File

robitashibhi < -

robitashibhi < d

robitashibhi < +

robitashibhi < s

- There are  
(i) One b  
(ii) Two  
(iii) One-k

There are two schemes of input buffering.

(i) One buffer Scheme

(ii) Two buffer Scheme

(i) One-buffer Scheme

```
int main()
{ }
```

↓ LBP

int main() { } EOF

↑ FP

Output

Stream of tokens

int - Token 1

main - Token 2

{ - Token 3

} - Token 4

(ii) Two-buffer Scheme

```
int i, j;
i = i + 1;
```

↓ LBP

int i, j; EOF

↑ FP

|   |   |   |   |   |   |     |  |  |
|---|---|---|---|---|---|-----|--|--|
| i | = | i | + | 1 | ; | EOF |  |  |
|---|---|---|---|---|---|-----|--|--|

(i) Rec

### Output

int - Token 1

i - Token 2

J = Token 3

i = Token 4

= - Token 5

i = Token 6

+ = Token 7

1 = Token 8

Gen

follo

(i) T

b

clou

is

By using two-buffer scheme system performance increases compared with one buffer scheme.

25/03/2022

The

### Recognition of Tokens

Tokens are recognized with the help of transition diagrams.

There are 5 types:-

(i) Recognition of Identifier

(ii) Recognition of Delimiter

(iii) Recognition of Relational Operator.

(iv) Recognition of keywords.

(v) Recognition of numbers.

28/03/

(ii) Re

B

know

The

## (i) Recognition of Identifier:

Generally, in C language there are some rules to be followed for identifiers.

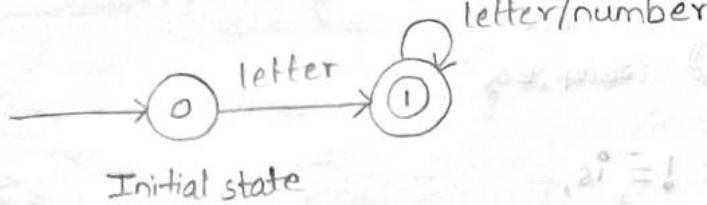

- (i) Identifier should start with letter.
- (ii) After first character, next character / data element may be character or number.

Now, the production rule for recognizing for the identifier is

is

letter (letter | number)\*

The transition diagram for above rule is

28/03/2022

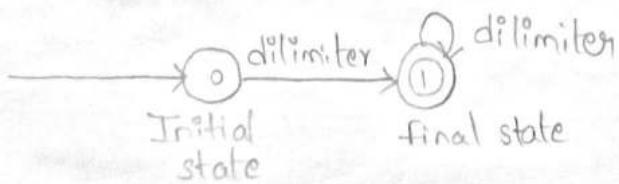

## (ii) Recognizer of De-limiter

Blank Space (\b), tab space (\t), new line character (\n) are known as De-limiter. These de-limiter creates white space.

The production rule for recognition of De-limiter is

delimiter (delimiter)\*

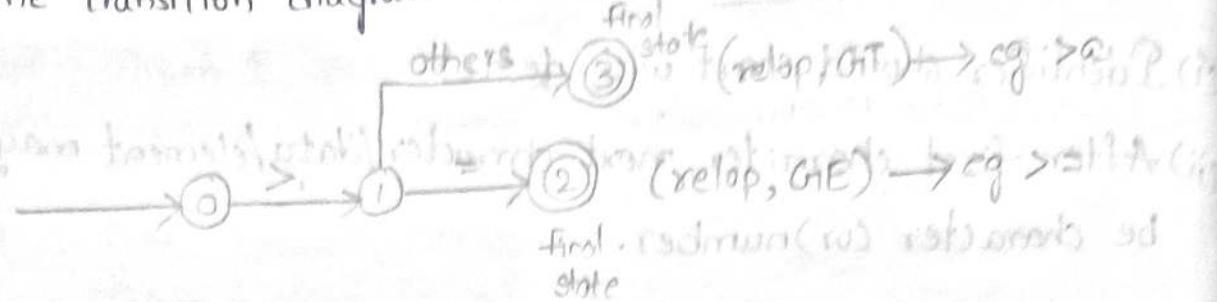

The transition diagram for de-delimiters is

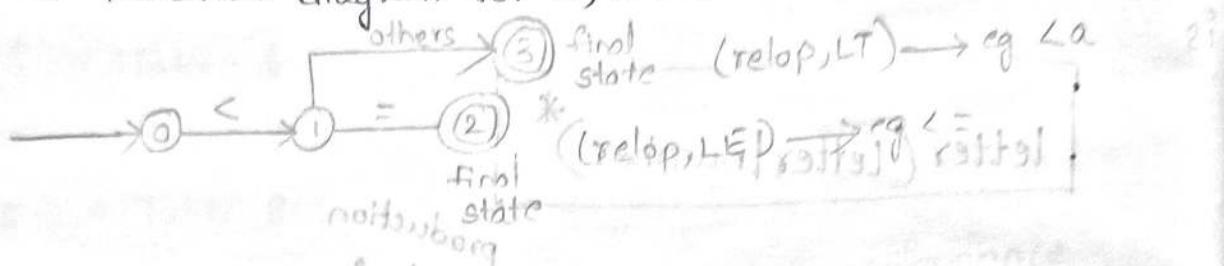

### (iii) Recognition of Relational Operators

The relational operators are  $>$ ,  $\geq$ ,  $<$ ,  $\leq$ ,  $=$ ,  $\neq$ .

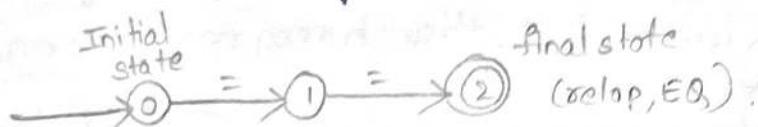

The transition diagram for  $>$ ,  $\geq$  is

The transition diagram for  $<$ ,  $\leq$  is

The transition diagram for  $= \neq$  is,

The transition diagram for  $!=$  is,

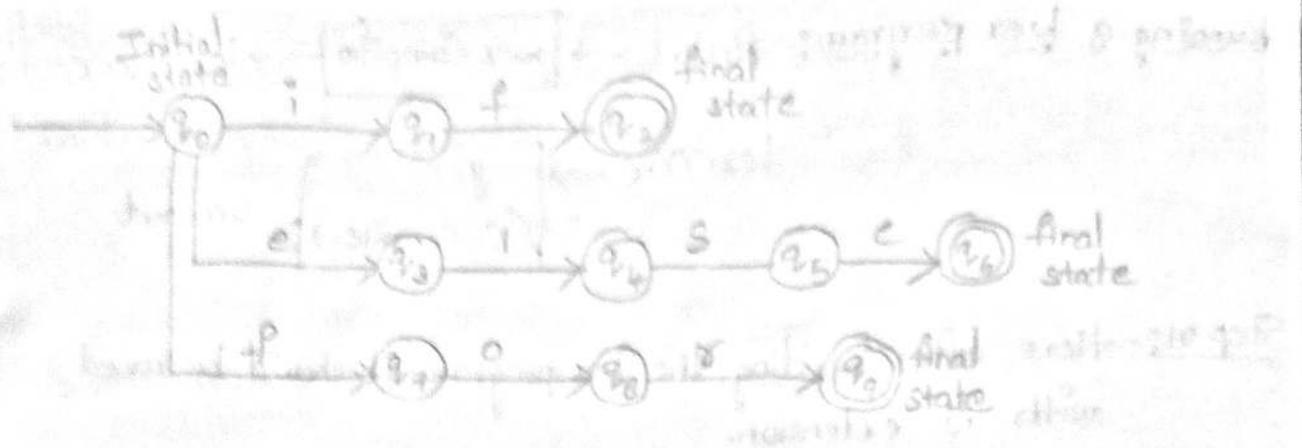

30/03/2022

### (iv) Recognition of Keywords

Keywords are also known as pre-defined words. Some of the keywords are if, else, for.

The transition diagram for above keywords is

if, else, for

#### (v) Recognition of numbers

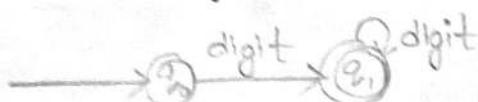

Number is defined as a digit or group of digits.

Ex:- 6, 29, 3.45, 1234567890, 123.4567890, 1234567890.1234567890

Production rule of numbers:

$$\text{number} = \text{digit} (\text{digit})^*$$

The transition diagram for numbers is

The Lexical Analyser Generator lex:-

Syntax of lex program.

header files  
and Macros

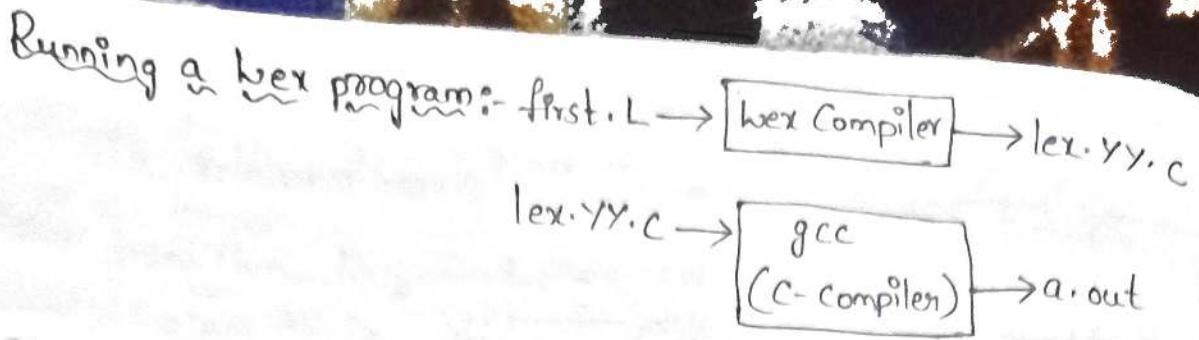

```
% { to be grouped or paired & atomatik stink
  to == and FT. digits no numbers & not atomatik
  % }
```

rules &  
definition

```
%%. ===== atomatik stink no
%. %. 
```

Main  
function

```
main()
{
    yy.lex();
}
```

Step 01:- Here after writing the lex program it should be saved with .l extension.

Step 02:- Lex program should be given to lex compiler. It generates a C program known as lex.yy.c

Step 03:- Now the C program (lex.yy.c) should be given to C-compiler. Now, the C-compiler generates a.out.

By executing a.out file we get output.

Commands:-

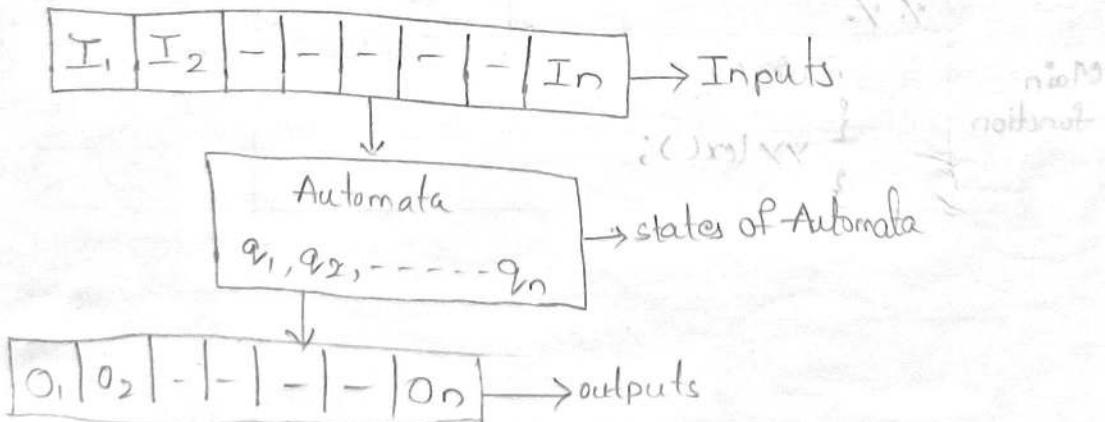

>flex first.l  
>gcc lex.yy.c  
>/a.out

This is how we can run lex program with linux.

### finite Automata

finite Automata is used to recognize set of patterns. finite automata has 5 elements or 5 tuples. It has set of states and rules.

The diagram for finite automata is

01/04/2022

(new(1) 11) part 2/3/2022

Finite Automata consists of the following elements

$$FA = \{Q, \Sigma, q_1, F, \delta\}$$

$Q$  → Finite set of states.

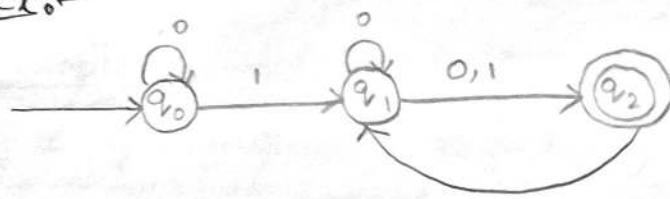

$\Sigma$  → set of input symbols

$q_1$  → Initial state

$F$  → set of final states.

$\delta$  → Transition function.

Ex:-

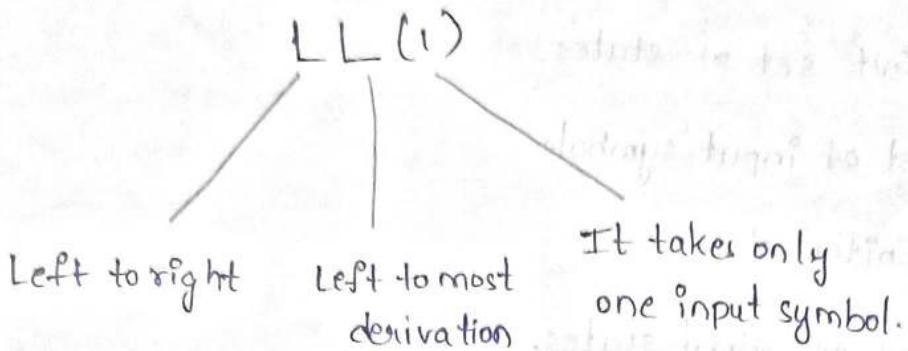

The transition table for above diagram is

| Present state | Input (0)  | Input (1) |
|---------------|------------|-----------|
| $q_0$         | $q_0$      | $q_1$     |
| $q_1$         | $q_1, q_2$ | $q_2$     |
| $q_2$         | $q_1$      | —         |

## Predictive Parsing (LL(1) parser) :-

It compares the statement with the given grammar & tells whether the given statement is correct or not.

Data structure used in LL(1) parser are :-

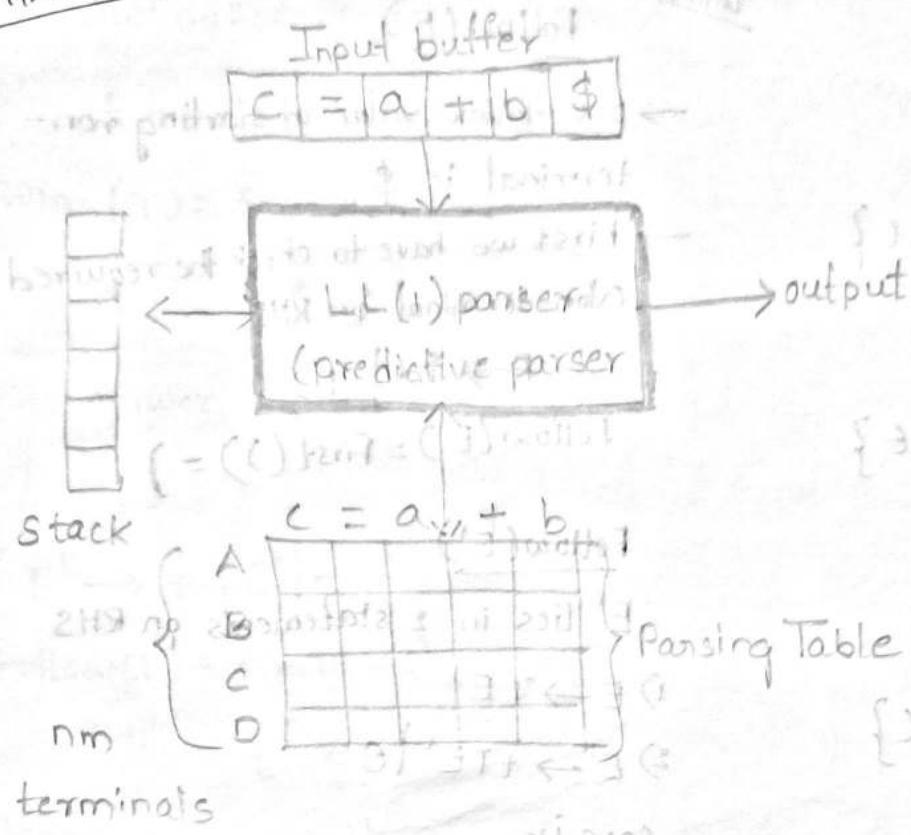

- i) Input buffer
- ii) Parsing table
- iii) Stack

i) Input buffer :- LL(1) parser stores the given statement in input buffer.

ii) Parsing table :- It converts given grammar into parsing table.

iii) Stack :- With the help of parsing table & stack concept LL 1 parser tells whether the given statements is correct (or) not.

6/04/2022

Example  $\{ \cdot \} = (\cdot) \text{wall} \cdot = (' \cdot ) \text{wall} \cdot$

| given grammar                       | First(NT)                          | Follow(NT)                       | (?) for it                       |
|-------------------------------------|------------------------------------|----------------------------------|----------------------------------|
| $E \rightarrow TE'$                 | $\{\text{id}, (\}\}_{\text{wall}}$ | $\{ \$, )\}_{\text{wall}}$       | $\{ \$, )\}_{\text{wall}}$       |
| $E' \rightarrow +TE' \mid \epsilon$ | $\{ +, \epsilon\}_{\text{wall}}$   | $\{ \$, )\}_{\text{wall}}$       | $\{ \$, )\}_{\text{wall}}$       |
| $T \rightarrow FT'$                 | $\{\text{id}, (\}\}_{\text{wall}}$ | $\{ +, \$, )\}_{\text{wall}}$    | $\{ +, \$, )\}_{\text{wall}}$    |
| $T' \rightarrow *FT' \mid \epsilon$ | $\{ *\}_{\text{wall}}$             | $\{ +, \$, )\}_{\text{wall}}$    | $\{ +, \$, )\}_{\text{wall}}$    |
| $F \rightarrow \text{id} \mid (E)$  | $\{\text{id}, (\}\}_{\text{wall}}$ | $\{ *, +, \$, )\}_{\text{wall}}$ | $\{ *, +, \$, )\}_{\text{wall}}$ |

Follow(NT) first(NT/KIT)

To convert given grammar into parsing table we have to find out first(Non-Terminal) and follow(Non-Terminals)

$(\cdot) \text{wall} = (\cdot) \text{wall} \cdot$   
 $\{ \cdot, + \}$

## First(E)

$$\text{First}(E) = T$$

$$\text{First}(T) = F$$

$$\text{First}(F) = \{\text{id}, ()\}$$

## First(E')

$$\text{First}(E') = \{+, \epsilon\}$$

## First(T)

$$\text{First}(T) = F$$

$$\text{First}(F) = \{\text{id}, ()\}$$

## First(T')

$$\text{First}(T') = \{*, \epsilon\}$$

## First(F)

$$\text{First}(F) = \{\text{id}, ()\}$$

28/04/2022

## Follow(E)

→ one follow value of starting non-terminal is \$.

→ First we have to check the required non-terminal on RHS

$$F \rightarrow \text{id} | (E)$$

$$\text{Follow}(E) = \text{First}(()) = )$$

## Follow(E')

E' lies in 2 statements on RHS

$$1) E \rightarrow TE'$$

$$2) E' \rightarrow +TE' | \epsilon$$

case i:-

$$\text{Follow}(E') = \text{Follow}(E) = \{\$\}, )\}$$

case ii:-

$$\text{Follow}(E') = \text{Follow}(E') = \{\$\}, )\}$$

## Follow(T)

T lies in 2 statements on RHS

$$1) E \rightarrow TE'$$

$$2) E' \rightarrow +TE' | \epsilon$$

case i:-

$$\text{Follow}(T) = \text{Follow}(E') = \{\$\}, )\}$$

case ii:-

$$\text{Follow}(T) = \text{Follow}(E') = \{\$\}, )\}$$

## Follow(T')

$$\text{Case (i):- } \text{Follow}(T) = \text{First}(E') \\ = \{+, \epsilon\}$$

Now substit

$E \rightarrow$

$\text{Follow}(T)$

Final ansu

Case (ii):-

$E' \rightarrow$

$\text{Follow}(T)$

Substit  
we get

$\text{Follow}$

final

## Follow

$T'$  lie

1)  $T$ .

2)  $T'$

Case ii

Now substitute  $\epsilon$  in  $E'$  of given statement

$$E \rightarrow T$$

$$\text{Follow}(T) = \text{Follow}(E)$$

$$= \{\$, )\}$$

Final answer in case 1 is  $\{+, \$, )\}$

Case (ii):-

$$E' \rightarrow + TE' | \epsilon$$

$$\text{Follow}(T) = \text{First}(E')$$

$$= \{+, \epsilon\}$$

Substitute  $\epsilon$  in  $E'$  of given statement

we get

$$E' \rightarrow + T$$

$$\text{Follow}(T) = \text{Follow}(E)$$

$$= \{\$, )\}$$

final Answer =  $\{+, \$, )\}$

Follow( $T'$ )

$T'$  lies in 2 statements on RHS

$$1) T \rightarrow FT'$$

$$2) T' \rightarrow *FT' | \epsilon$$

Case (i):-  $\text{Follow}(T') = \text{Follow}(T)$

$$= \{+, \$, )\}$$

Case (ii) :-

$$\begin{aligned}\text{Follow}(T') &= \text{Follow}(T') \\ &= \{+, \$, )\}\end{aligned}$$

final answer is  $\{+, \$, )\}$

Follow(F)

F lies in 2 statements in RHS

- 1)  $T \rightarrow FT'$
- 2)  $T' \rightarrow *FT' | \epsilon$

Case (i) :-

$$\begin{aligned}\text{Follow}(F) &= \text{first}(T') \\ &= \{\ast, \epsilon\}\end{aligned}$$

Now substitute  $\epsilon$  in  $T'$  in given statement

$$T \rightarrow F$$

$$\begin{aligned}\text{Follow}(F) &= \text{Follow}(T) \\ &= \{+, \$, )\}\end{aligned}$$

Final answer is  $\{\ast, +, \$, )\}$

Case (ii) :-

$$\begin{aligned}\text{Follow}(F) &= \text{first}(T') \\ &= \{\ast, \epsilon\}\end{aligned}$$

Now substitute  $\epsilon$  in  $T'$  in given statement

$$T' \rightarrow *F$$

$$\begin{aligned}\text{Follow}(F) &= \text{Follow}(T') \\ &= \{+, \$, )\}\end{aligned}$$

## Construction of Predictive Parsing table

|    | +                     | *                     | (                   | )                         | id                  | \$                        |
|----|-----------------------|-----------------------|---------------------|---------------------------|---------------------|---------------------------|
| E  |                       |                       |                     |                           | $E \rightarrow TE'$ |                           |
| E' | $E' \rightarrow +TE'$ |                       |                     |                           | $E' \rightarrow E$  | $E' \rightarrow \epsilon$ |
| T  |                       |                       | $T \rightarrow FT'$ |                           | $T \rightarrow FT'$ |                           |
| T' | $T' \rightarrow E$    | $T' \rightarrow *FT'$ |                     | $T' \rightarrow \epsilon$ |                     | $T' \rightarrow \epsilon$ |
| F  |                       |                       | $F \rightarrow (E)$ |                           | $F \rightarrow id$  |                           |

### Rule 1:-

If the production rule is in the form of  $A \xrightarrow{\text{dot}} \alpha$ , then find first( $\alpha$ ). We get terminal values as answers.

In the table at terminal cells fill the rule  $A \xrightarrow{\text{dot}} \alpha$ .

### Rule 2

If the production rule is  $A \xrightarrow{\text{dot}} \epsilon$  in the form of  $A \xrightarrow{\text{dot}} \epsilon$ , then find follow(A), we get terminal values as answer.

In the table at terminal cells, fill the rule  $A \xrightarrow{\text{dot}} \epsilon$ .

1)  $E \rightarrow TE'$

$\text{First}(T) = \{\text{id}, (\}$ ; Fill  $E \rightarrow TE'$  at id & ( in table

2)  $E' \rightarrow +TE' | \epsilon$

$\text{First}(T) = \{\text{id}, (\}$

$\text{First}(+) = \{+\}$

So, fill  $E' \rightarrow +TE'$  at + in table

$E' \rightarrow E$

$\text{Follow}(E') = \{\$, )\}$

So, fill  $E' \rightarrow E$  at  $\$$  and at  $)$  in table.

3)  $T \rightarrow FT'$

$\text{First}(F) = \{\text{id}, C\}$

So, fill  $T \rightarrow FT'$  at  $\text{id}$  & at  $C$  in table

4)  $T' \rightarrow *FT'$

4)  $T' \rightarrow *FT' | \epsilon$

$T' \rightarrow *FT'$

$\text{First}(\ast) = \{\ast\}$

So, fill  $T' \rightarrow *FT'$  at  $\ast$  in table

$T' \rightarrow E$

$\text{Follow}(T') = \{+, \$, )\}$

So, fill  $T' \rightarrow E$  at  $+$ ,  $\$$ ,  $)$  in table.

5)  $F \rightarrow \text{id} | (E)$

$F \rightarrow \text{id}$

$\text{First}(\text{id}) = \{\text{id}\}$

So, fill  $F \rightarrow \text{id}$  at  $\text{id}$  in table

$F \rightarrow (E)$

$\text{First}(C) = (C)$

So, fill  $F \rightarrow (E)$  at  $C$  in table

Example

$w = \text{id} * \text{id} .$

### From Regular Expressions to Automata

1)  $b a^* b \rightarrow ba^0 b, ba^1 b, ba^2 b, ba^3 b, \dots$   
bb, bab, baab, baaab, baaaab, ...

After expanding regular expression is shown above.

The finite Automata for above regular expression is

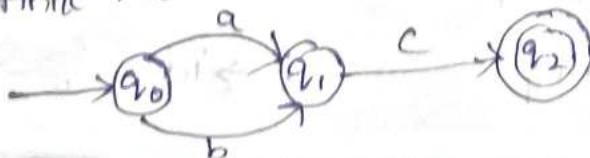

2)  $(a+b)c$

After expanding regular expression is as follows

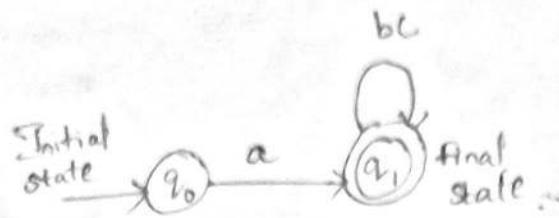

The given expression can also be written as

(a OR b)c

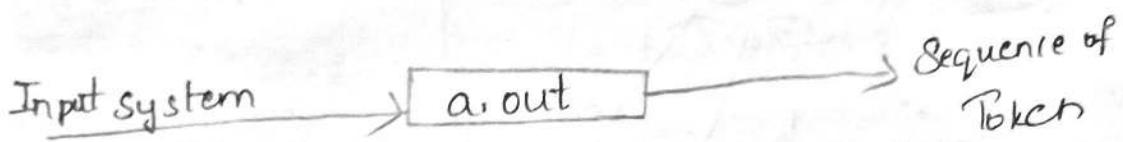

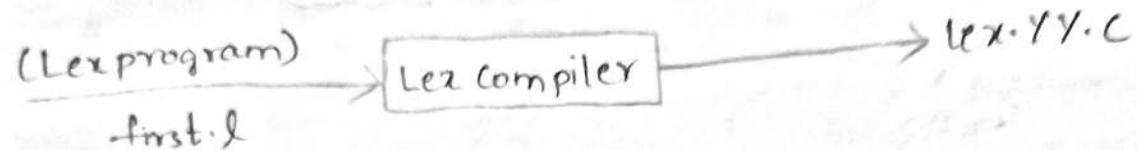

The finite Automata for the above regular expression is

3)  $a(bc)^*$

## Design of a lexical Analyzer Generator

### Step 01:-

Generally, lex program is save with .l extension.

The lex programs should be given to lex ~~prog~~ compiler. Lex compiler converts lex program to C program which is in the form of lex.yy.c

### Step 02,-

In this phase C program is given to C compiler which is converted into an executable file a.out.

### Step 03:-

In this phase an input stream (c=atb) is given to an executable file a.out.

Here a.out generates a sequence of tokens from the given input stream. So the output is c → id

c - id

= - operator

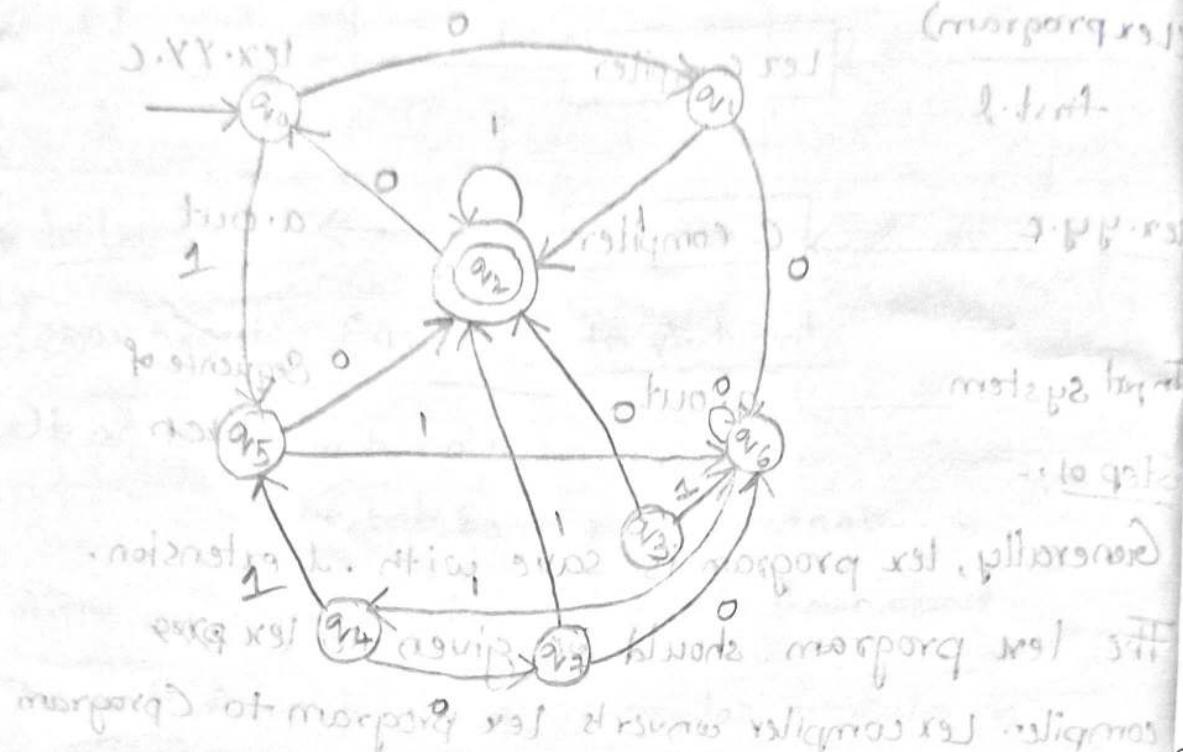

a - id

+ - operator

b - id

12/04/2022

## Optimization of DFA based pattern matchers

Compressing the above finite automata is also known as optimization of finite automata.

Transition table for the above DFA is:

State    0    1

$\rightarrow q_0 \xrightarrow{0} q_1, q_0 \xrightarrow{1} q_1$  (distinguishable as starting with 0)

$\rightarrow q_1 \xrightarrow{0} q_2, q_1 \xrightarrow{1} q_2$  (distinguishable as starting with 1)

$\rightarrow q_2 \xrightarrow{0} q_3, q_2 \xrightarrow{1} q_4$  (distinguishable as starting with 0)

$q_3$

$q_4$

$q_5$

$q_6$

$q_7$

Step 01:-

Set of Q = { $q_0$ ,

from above set

states

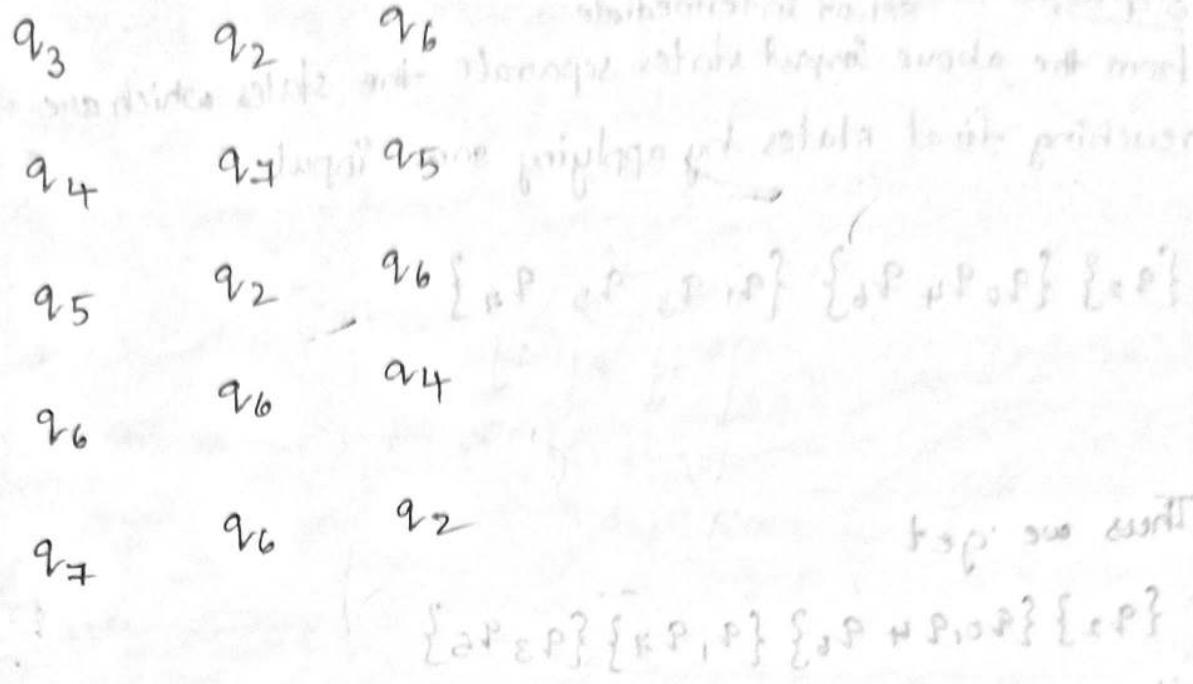

Final state is  
intermediate

Step 02:-

Find out the  
state by applying

{ $q_2$ } { $q_0, q_1$ }

Thus we get  
{ $q_2$ } { $q_0, q_1$ }

Step 01:-

Set of  $Q = \{q_0, q_1, q_2, q_3, q_4, q_5, q_6, q_7\}$   
 from above set of  $Q$ , separate final states and intermediate states

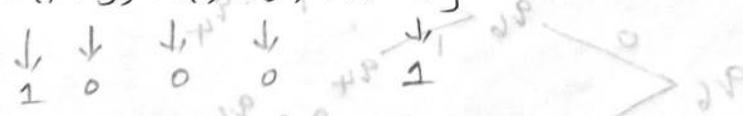

Final state is  $\{q_2\}$

Intermediate states are  $\{q_0, q_1, q_3, q_4, q_5, q_6, q_7\}$

Step 02:-

Find out the intermediate states which are reaching final state by applying any type of input and separate them.

$\{q_2\} \{q_0, q_1, q_3, q_4, q_5, q_6, q_7\}$

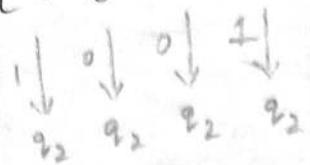

Thus we get

$\{q_2\} \{q_0, q_4, q_6\} \{q_1, q_3, q_5, q_7\}$

Step 03:-

From the above input states separate the states which are reaching final states by applying same input.

$$\{q_2\} \{q_0, q_4, q_6\} \{q_1, q_3, q_5, q_7\}$$

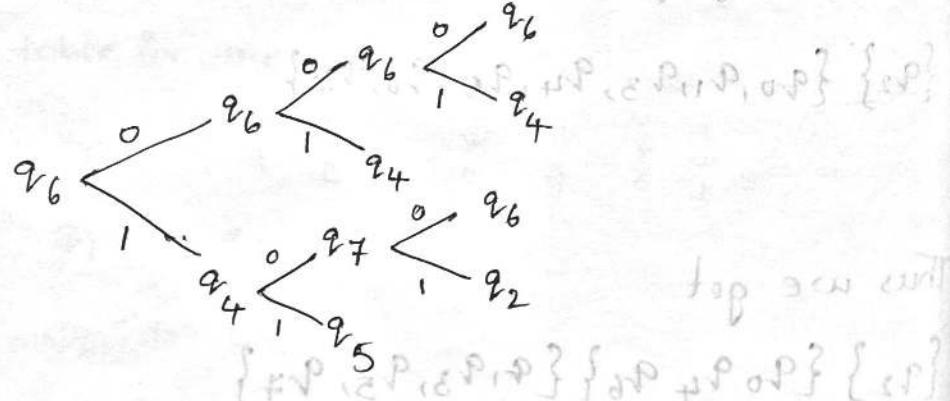

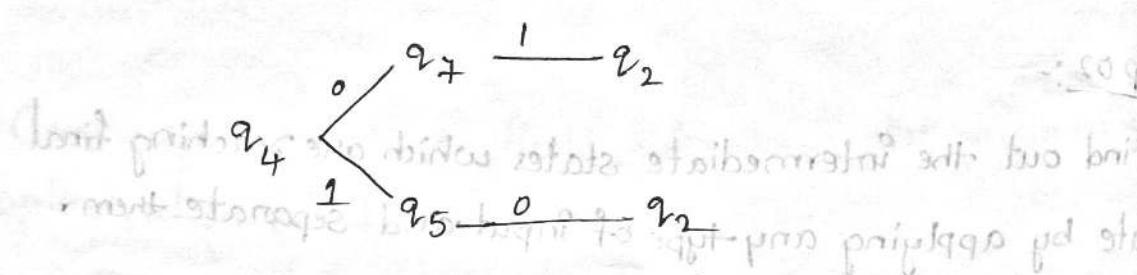

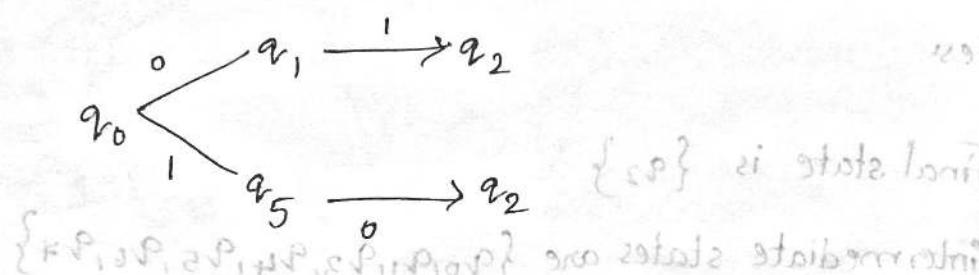

Thus we get

$$\{q_2\} \{q_0, q_4, q_6\} \{q_1, q_7\} \{q_3, q_5\}$$

Step 04:-

Let us take set  $\{q_0, q_4, q_6\}$  and subdivide it by considering reaching the final state in one step.

So, from the different.

So, the inter

$$\{q_2\} \{q_0, q_1\}$$

The transition  
is:

States

$$\{q_2\}$$

$$\{q_3, q_5\}$$

E

$$*\{q_2\}$$

$$\{q_6\}$$

key vs  
state

$\rightarrow A$

B

C

$* E$

D

So, from the above diagram  $q_0, q_4$  are similar and  $q_6$  is different.

So, the intermediate codes we get are

$$\{q_2\} \{q_0, q_4\} \{q_6\} \{q_1, q_7\} \{q_3, q_5\}$$

The transition table for the above set of intermediate codes is:

| States                         | 0              | 1              |
|--------------------------------|----------------|----------------|
| $\xrightarrow{A} \{q_0, q_4\}$ | $\{q_1, q_7\}$ | $\{q_3, q_5\}$ |
| $\{q_1, q_7\}$                 | $\{q_6\}$      | $\{q_2\}$      |
| $\{q_3, q_5\}$                 | $\{q_2\}$      | $\{q_6\}$      |
| $*\{q_2\}$                     | $\{q_0, q_4\}$ | $\{q_2\}$      |
| $\xrightarrow{D} \{q_6\}$      | $\{q_6\}$      | $\{q_0, q_4\}$ |

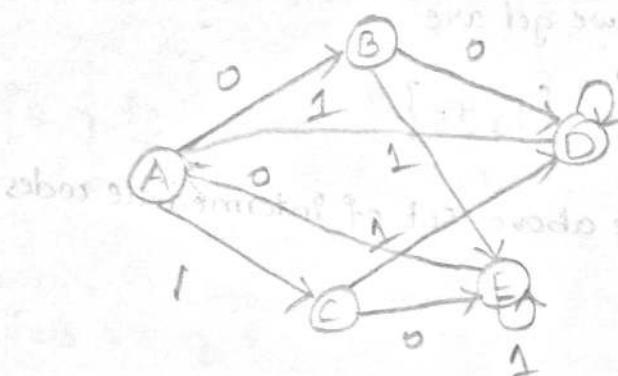

Optimized DFA transition table

Let us

| State             | 0 | 1 |
|-------------------|---|---|
| $\xrightarrow{A}$ | B | C |
| B                 | D | E |
| C                 | E | D |
| $*E$              | A | E |
| D                 | D | A |

Now let us draw the optimized transition diagram is

## UNIT-2

### Part-1

## Syntax Analysis

### Introduction

- \* Syntax analysis is the second phase of the compiler design. It checks syntactical structure of given input. i.e., it checks whether given input is correct or not.
- \* Syntax analysis generates a syntax tree or parse tree to find the given input is correct or not.
- \* The syntax is generated from the given grammar.

Eg:-

Given grammar

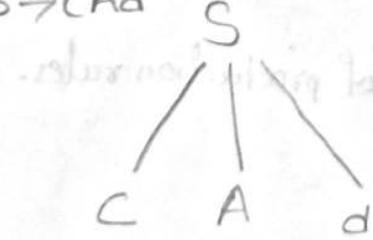

$$S \rightarrow CAd$$

$$A \rightarrow bc/a$$

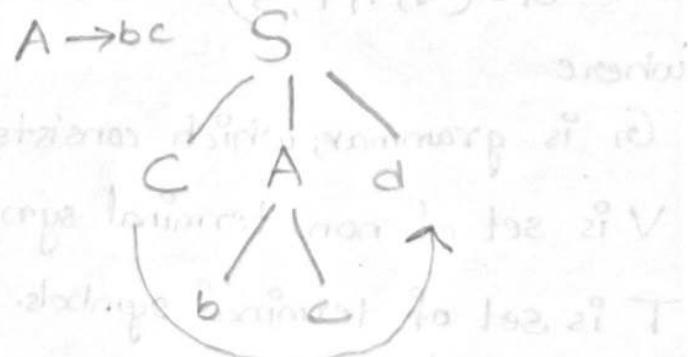

Given Input string is Cad

Check whether Input string is correct or not for given grammar.

$$S \rightarrow CAd$$

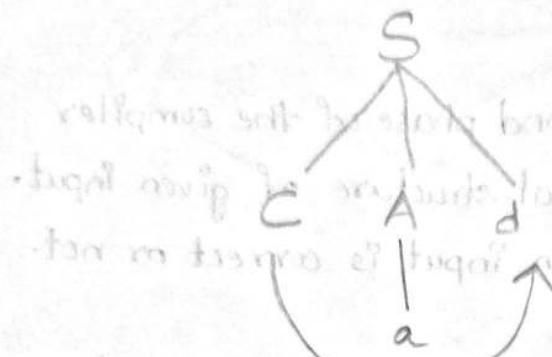

$$A \rightarrow bc$$

As per the obtained syntax tree the given input is not matching with the leaf node.

So, backtracking and substitute  $A \rightarrow a$

In the above tree the output is matching with the given input. So, the given input is syntactically correct input.

19/04/2022

### Context-free Grammar

A Context-free grammar is a formal grammar, which is used to generate all the possible patterns of strings.

It is defined as a 4 tuples:

$$G_1 = (V, T, P, S)$$

where

$G_1$  is grammar, which consists of set of production rules.

$V$  is set of non-terminal symbols.

$T$  is set of terminal symbols.

$P$  is set of production rules which are used to replace non-terminals.

$S$  is starting symbol used to derive the string.

Example: Construct CFG for the language having any no. of a's over the set  $S = \{a\}$ .

Sol:-  $RE \Rightarrow a^*$

production rules for above RE is

$S \rightarrow aS \rightarrow \text{rule 1}$

$S \rightarrow \epsilon \rightarrow \text{rule 2}$

The series of  $a^*$  is

a, aa, aaa, aaaa, aaaaa

Let us derive aaaaa is correct for above grammar.

$S \rightarrow \text{start symbol}$

$aS \rightarrow \text{rule 1}$

$aas \rightarrow \text{rule 1}$

$aaas \rightarrow \text{rule 1}$

$aaaas \rightarrow \text{rule 1}$

$aaaaas \rightarrow \text{rule 1}$

$aaaaaa \epsilon \rightarrow \text{rule 2}$

$\therefore$  aaaaa is correct.

The string aaaaa is correct for above given grammar.

## Top-down parsing

In Top-down parsing technique parse-tree is constructed from top to bottom. Here the input is read from left to right.

→ Here parse tree is generated from starting symbol.

Let us consider an example where grammar is given and you need to construct a parse tree by using Top-down parsing technique to obtain given input string.

Given grammar  
→  $S \rightarrow aABe$

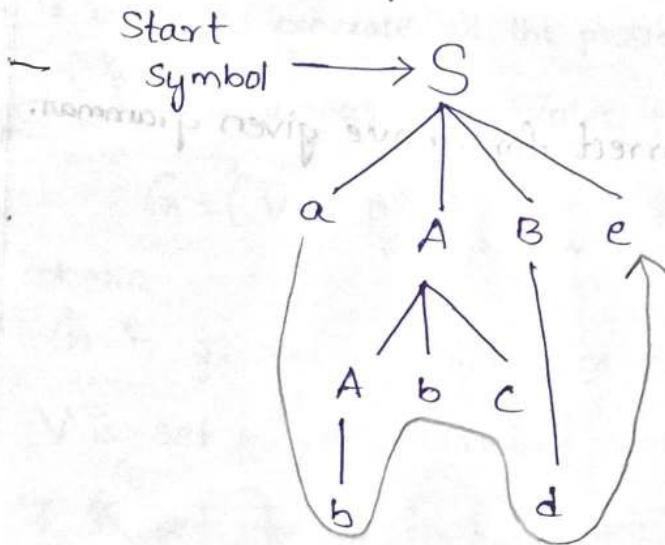

$A \rightarrow Abc/b$

$B \rightarrow d$

Given input string

abbcde

Top down parsing to obtain Input string.

## Bottom-Up parsing

- Bottom-Up parsing will start from Input string and move to the start symbol of the grammar.
- It will follow rightmost derivation in reverse order.

Let us consider an example where grammar is given and you need to construct a parse tree by using Bottom up parsing technique.

Given grammar

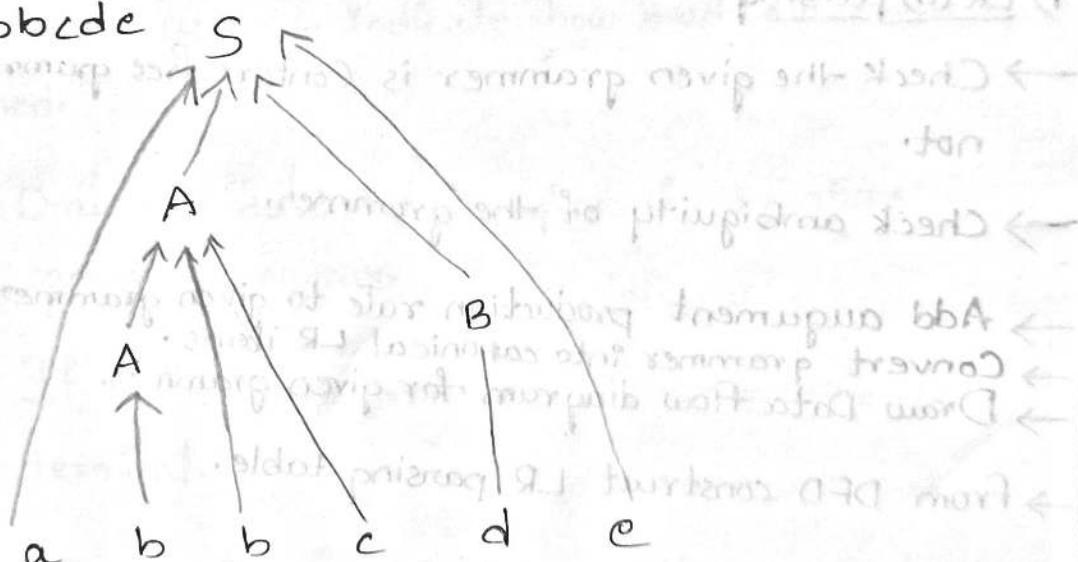

$$S \rightarrow aABe$$

$$A \rightarrow Abc \mid b$$

$$B \rightarrow d$$

Given Input string

abbcde

## Part-2

### Introduction to LR Parsing

→ It is also known as shift Reduce bottom up parsing.

→ In LR( $K$ ) → L means left to right scanning the input.

R means construction of right most derivation.

in Reverse order

K means Look-a-head value.

→ LR parsing is classified into 4 types.

- 1) LR(0)
  - 2) Simple LR (SLR)
  - 3) Look-a-head LR (LALR)
  - 4) Canonical LR (CLR)
- $\left. \begin{array}{l} \text{LR}(0) \\ \text{SLR} \\ \text{LALR} \\ \text{CLR} \end{array} \right\}$
- ↓  
Powerfull

#### D LR(0) parsing

→ Check the given grammar is Context free grammar (or) not.

→ Check ambiguity of the grammar.

→ Add augment production rule to given grammar.

→ Convert grammar into canonical LR items.

→ Draw Data flow diagram for given grammar.

→ from DFD construct LR parsing table.

Example

Given

S-

A-

Step 01

Step 02

Step 03

Rule 1

Rule 2

Rule 3:

### Example,

Given grammar

$$S \rightarrow AA$$

$$A \rightarrow aAb$$

ns:-

Step 01 :- Add argument production rule to given grammar.

$$S' \rightarrow S \rightarrow \text{argument production rule}$$

$$S \rightarrow AA$$

$$A \rightarrow aA|b$$

Step 02 :- Convert grammar into canonical LR items.

$$S' \rightarrow \cdot S$$

$$S \rightarrow \cdot AA$$

$$A \rightarrow \cdot aA | \cdot b$$

LHS

RHS

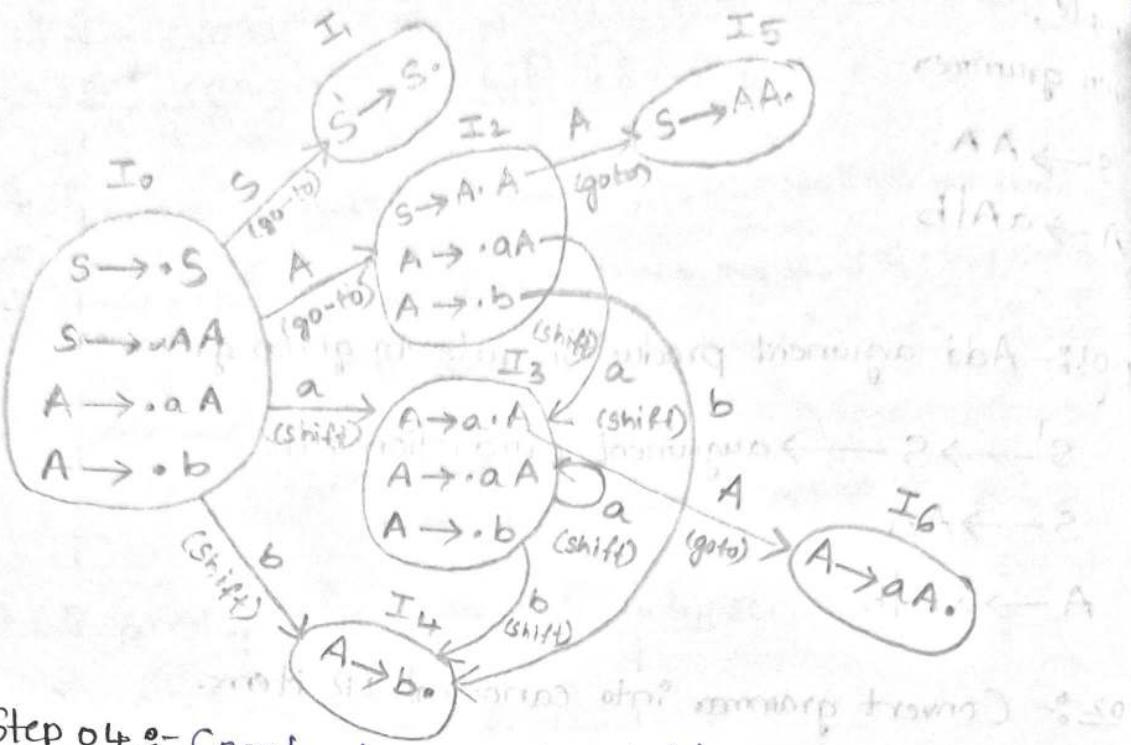

→ Here  $\cdot$  is used to indicate how much of Input  $^9s$  has been scanned.

Step 03 :- Draw the data flow diagram for the above canonical grammar.

Rule 1 :- If  $\cdot$  is before non-terminal expand the non-terminal.

Rule 2 :- If  $\cdot$  is before terminal no need to expand.

Rule 3 :- If  $\cdot$  arrives at end it indicates scanning is completed.

Step 04 :- Construct a parsing table.

Parsing Table :-

Rule 1 :- If a state is going to another state by applying a non-terminal then it is called as go-to.

Rule 2 :- If a state is going to another state by applying terminal then it is called as shift.

Rule 3 :- If a state is having final item write reduce node completed.

22/04/2022

### Simple LR (SLR)

- It is also known as Simple LR parser.
- It works on Simplest class of grammar.
- It contains few no. of states.
- SLR parser technique is simple and fast to construct parsing table.
- In SLR we place the reduce only in the follow of LHS production not in entire row.

Given grammar

$$A \rightarrow (A) | a$$

Step 01:- Add augment production rule to the given grammar.

$$A' \rightarrow A \rightarrow \text{augment production rule}$$

$$A \rightarrow (A)$$

$$A \rightarrow a$$

Step 02:- Convert grammar into canonical LR items.

$$A' \rightarrow \cdot A$$

$$A \rightarrow \cdot (A)$$

$$A \rightarrow \cdot a$$

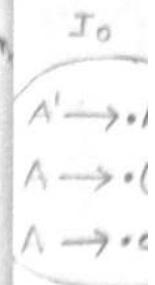

→ Here • is used to indicate how much of Input is scanned.

Step 03:- Draw the data flow diagram for the above canonical grammar.

Rule 1:- If • is before non-terminal expand the non-terminal.

Rule 2:- If • is before terminal no need to expand.

Rule 3:- If • arrives at end it indicates scanning is completed.

Step 04

Parsing

Rule 1

Rule 2

Rule 3

State

$I_0$

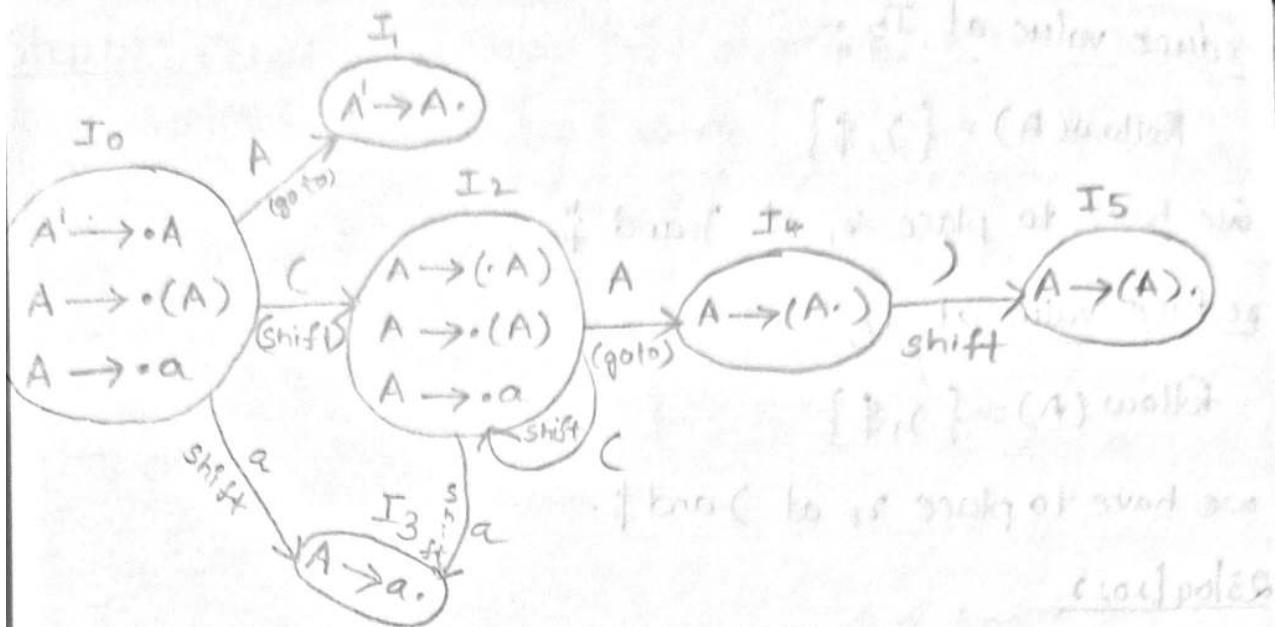

$I_1$

$I_2$

$I_3$

$I_4$

$I_5$

Step 04 :- Construct a parsing table.

#### Parsing table

Rule 1 :- If a state is going to another state by applying a non-terminal then it is called as go-to.

Rule 2 :- If a state is going to another state by applying terminal then it is called as shift.

Rule 3 :- If a state is having final item write reduce note completed.

| State   | Shift<br>(Action) |         |              |              | goto |
|---------|-------------------|---------|--------------|--------------|------|
|         | a                 | c       | )            | \$           | A    |
| \$I_0\$ | \$I_3\$           | \$I_2\$ |              |              | 1    |
| \$I_1\$ |                   |         |              | accept       |      |
| \$I_2\$ | \$I_3\$           | \$I_2\$ |              |              | 4    |
| \$I_3\$ |                   |         | \$\alpha_2\$ | \$\alpha_2\$ |      |
| \$I_4\$ |                   |         |              | \$I_5\$      |      |
| \$I_5\$ |                   |         | \$\alpha_1\$ | \$\alpha_1\$ |      |

reduce value at  $I_3$ :

$$\text{Follow}(A) = \{ , \} , \{ \}$$

We have to place  $r_1$  at  $,$  and  $\$$

reduce value at  $I_5$ :

$$\text{follow}(A) = \{ , \} , \{ \}$$

We have to place  $r_1$  at  $,$  and  $\$$ .

23/04/2022

Canonical LR (CLR) :-

→ CLR is a powerful parsing technique.

→ It is also known as LR(1) parsing technique.

→  $\text{LR}(1) = \text{LR}(0) + \text{Look-ahead value.}$

→ Here, we place reduce item at Look-ahead symbol in the parsing table.

Given grammar

$$E \rightarrow BB$$

$$B \rightarrow cB \mid d$$

Step 01:- Add augment production rule to the given grammar.

$$E' \rightarrow E \rightarrow \text{augment production rule.}$$

$$E \rightarrow BB$$

$$B \rightarrow cB$$

$$B \rightarrow d$$

Step 02:- Con

wit

$$E' \rightarrow E$$

$$E \rightarrow B$$

$$B \rightarrow cE$$

$$B \rightarrow d$$

→ Here  $c$  is scanned.

Step 03:- Draw

abo

Rule 1:- If

non

Rule 2:- If

Rule 3:- If

comp

Step 02:- Convert grammar into canonical LR items along with look-a-head values.

$E' \rightarrow \cdot E, \$ \xrightarrow{\text{look-a-head value}}$

$E \rightarrow \cdot B B, \$$

$B \rightarrow \cdot c B, c | d$

$B \rightarrow \cdot d, c | d$

→ Here  $\cdot$  is used to indicate how much of Input is scanned.

Step 03:- Draw the data flow diagram for diagram for the above grammar.

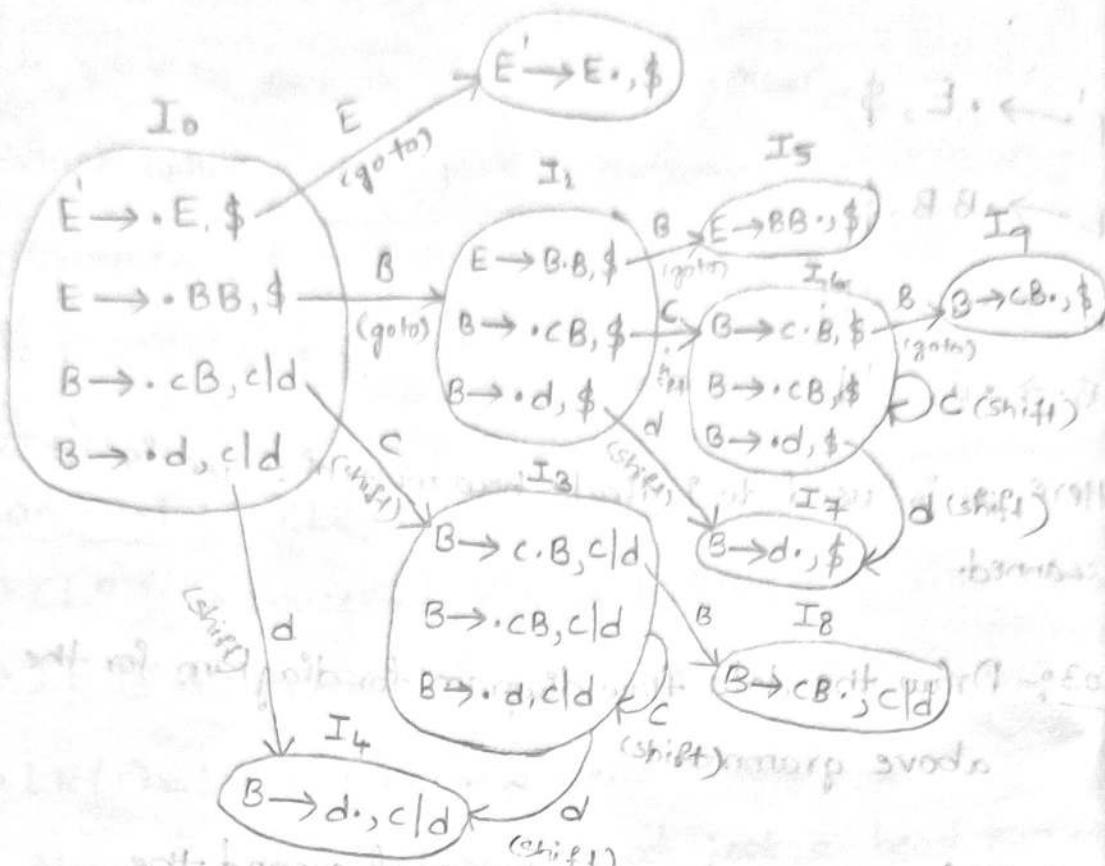

Rule 1:- If  $\cdot$  is before non-terminal expand the non-terminal.

Rule 2:- If  $\cdot$  is before terminal no need to expand.

Rule 3:- If  $\cdot$  arrives at end it indicates scanning is completed.

part A (construction of LR(0) items with scanning tokens)

initial, first, predict states

Step 04:- Construct a parsing table:

Parsing table

Rule 1 :- If a state is going to another state by applying a non-terminal then it is called as go-to.

Rule 2 :- If a state is going to another state by applying terminal then it is called as shift.

Rule 3 :- If a state is having final item write reduce rule completed.

| Shift State    | Shift          |                |                | go-to |   |
|----------------|----------------|----------------|----------------|-------|---|
|                | c              | d              | \$             | E     | B |

26/04/2022

### Look-a-head LR(LALR) parsing technique (LR(1))

$$LR(1) = LR(0) + \text{Look-a-head value}$$

→ LALR is powerful parsing technique than other parsing techniques.

→ When LALR is compared with CLR, LALR contains few no.of states.

→ As a result, execution speed will be increased.

Given grammar

$$E \rightarrow BB$$

$$B \rightarrow cB/d$$

Step 01: Add augmentation production rule to the given grammar.

$$E' \rightarrow E$$

$$E \rightarrow BB$$

$$B \rightarrow cB$$

$$B \rightarrow d$$

- Step 02: Convert grammar into canonical LR items along with look-a-head values.

$$E' \rightarrow \cdot E, \$$$

$$E \rightarrow \cdot BB, \$$$

$$B \rightarrow \cdot cB, c/d$$

$$B \rightarrow \cdot d, c/d$$

Now to calculate look-a-head values

$$1) E' \rightarrow \cdot E, \$ \rightarrow \begin{matrix} \text{look-a-head} \\ \text{value} \end{matrix}$$

The above rule is augmentation production rule.

So, by default look-a-head value is \$.

$$2) E' \rightarrow \cdot E, \$$$

We get second rule as given below.

After non-terminal E is present, so write production rule of E

$$E \rightarrow \cdot BB$$

We get look-a-head value in second rule as follows.

After E, we have to find first (non-terminal) If there is no non-terminal, look-a-head value is \$, so

$$E \rightarrow \cdot BB, \$$$

③ We get 3<sup>rd</sup> rule from 2<sup>nd</sup> production rule.

$$E \rightarrow \cdot BB, \$$$

After . non-terminal B is present, so write B production rule.

$$B \rightarrow \cdot cB$$

$$B \rightarrow \cdot d$$

Now we get look-a-head value as follows:

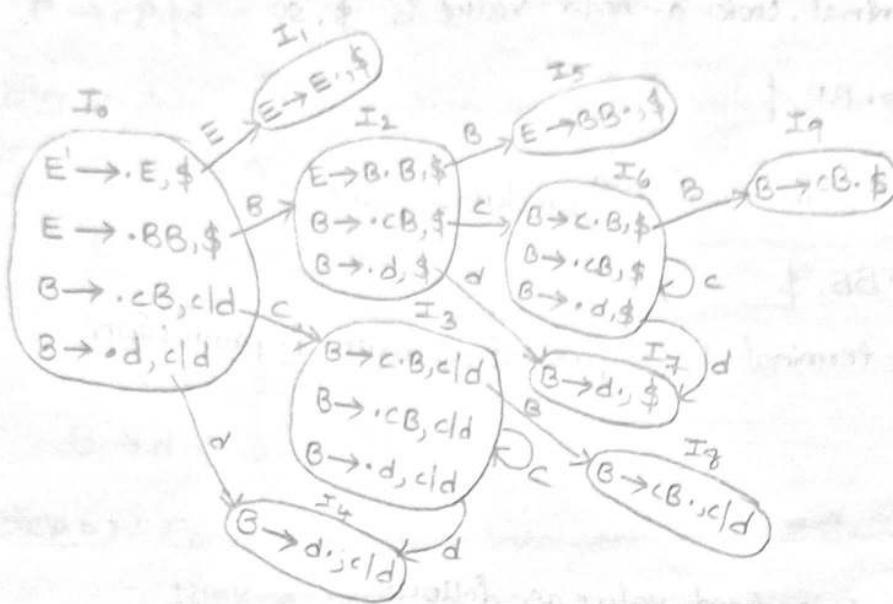

In second rule after B non-terminal is present, so to get look-a-head value we have to find first(B).

$$\text{first}(B) = c/d$$

So c/d is the look-a-head value in 3<sup>rd</sup> & 4<sup>th</sup> rule

$$B \rightarrow \cdot cB, c/d$$

$$B \rightarrow \cdot d, c/d$$

29/04/2022

### LALR parsing table for before merging

| States         | Shift          |                |                | goto |   |
|----------------|----------------|----------------|----------------|------|---|
|                | C              | d              | \$             | E    | B |
| I <sub>0</sub> | I <sub>3</sub> | I <sub>4</sub> |                |      |   |
| I <sub>1</sub> |                |                | Accept         |      |   |
| I <sub>2</sub> | I <sub>6</sub> | I <sub>#</sub> |                |      | 5 |
| I <sub>3</sub> | I <sub>3</sub> | I <sub>4</sub> |                |      | 8 |
| I <sub>4</sub> | R <sub>3</sub> | R <sub>3</sub> |                |      |   |
| I <sub>5</sub> |                |                | R <sub>1</sub> |      |   |
| I <sub>6</sub> | I <sub>6</sub> | I <sub>4</sub> |                |      | 9 |
| I <sub>7</sub> |                |                | R <sub>3</sub> |      |   |
| I <sub>8</sub> | R <sub>2</sub> | R <sub>2</sub> |                |      |   |
| I <sub>9</sub> |                |                | R <sub>2</sub> |      |   |

In DFD, the following states look-a-head different.

They are:-

- 1) I<sub>3</sub> and I<sub>6</sub> =
- 2) I<sub>4</sub> and I<sub>#</sub> =
- 3) I<sub>8</sub> and I<sub>9</sub> =

Now, merge above rules, different pro-

### LALR parsing table

| States         | Shift |   |    | goto |   |
|----------------|-------|---|----|------|---|
|                | C     | d | \$ | E    | B |
| I <sub>0</sub> |       |   |    |      |   |
| I <sub>1</sub> |       |   |    |      |   |
| I <sub>2</sub> |       |   |    |      |   |
| I <sub>3</sub> |       |   |    |      |   |
| I <sub>4</sub> |       |   |    |      |   |
| I <sub>5</sub> |       |   |    |      |   |
| I <sub>6</sub> |       |   |    |      |   |
| I <sub>7</sub> |       |   |    |      |   |
| I <sub>8</sub> |       |   |    |      |   |
| I <sub>9</sub> |       |   |    |      |   |

Before

After merging efficiency easy.

In DFD, the following states have same rules having different look-ahead values.

They are:-

$$1) I_3 \text{ and } I_6 = I_{36}$$

$$2) I_4 \text{ and } I_7 = I_{47}$$

$$3) I_8 \text{ and } I_9 = I_{89}$$

Now, merge above same states, having same production rules, different production rules.

LALR parsing table after merging

| States   | Shift    |          |        |   | goto        |                           |
|----------|----------|----------|--------|---|-------------|---------------------------|
|          | C        | d        | \$     | E | B1 + B2 → E | B1 + B2 → E               |
| $I_0$    | $I_3$    | $I_4$    |        | 1 | 2           | $3 \times 3 \leftarrow E$ |
| $I_1$    |          |          | Accept |   |             | $(B) \leftarrow E$        |
| $I_2$    | $I_6$    | $I_7$    |        |   | 5           | $I \leftarrow E$          |
| $I_{36}$ | $I_{36}$ | $I_{47}$ |        |   | 89          |                           |
| $I_{47}$ | $R_3$    | $R_3$    | $R_3$  |   |             | $E + S \rightarrow E$     |
| $I_5$    |          |          | $R_1$  |   |             |                           |
| $I_{89}$ | $R_2$    | $R_2$    | $R_2$  |   | 6           |                           |

Before merging there are 10 states in the parsing table.

After merging there are only 7 states. So, by doing this, efficiency & performance of the LALR algorithm will be easy.

30/04/2022

## Ambiguous Grammars

A grammar is said to be ambiguous if there exists:

(i) more than one left most derivation

(ii) more than one right most derivation

(iii) more than one parse trees for the given strings

If a grammar has ambiguity then it is not good for

computer construction.

Ex:- Let us consider a grammar with production rules.

$$E \rightarrow E + E$$

$$E \rightarrow E * E$$

$$E \rightarrow (E)$$

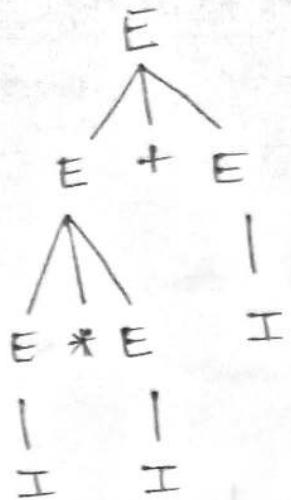

$$E \rightarrow I$$

$$I \rightarrow E | 0 | 1 | 2 | \dots | 9$$

Given string

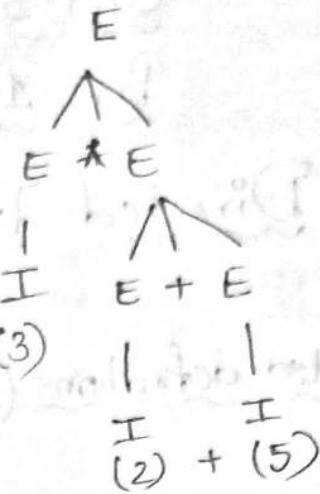

3 \* 2 + 5

for the given string the above grammar generates 2  
parse trees as given below.

(3) \* (2)

3 \* 2 + 5

3 \* 2 + 5

Since there are 2 parse trees for given string the above grammar is said to be ambiguity grammar. This grammar is not good for compiler constructions.

## Unit-3

### Part-1

# Syntax-Directed Translation

## Syntax-Directed definitions (SDD):

An

SDD = Context free grammar + Semantic rules.

An SDD is a context free grammar together with

- semantic rules

### Production Rule:

$$\begin{array}{l} E \rightarrow E + T \\ E \rightarrow T \end{array} \quad \left. \begin{array}{c} \text{CFG} \\ \checkmark \end{array} \right.$$

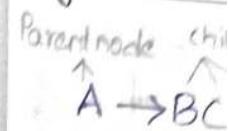

Grammar  
Symbols

### Semantic Rules

$$\begin{array}{l} E.\text{value} \rightarrow E.\text{value} + T.\text{value} \\ E.\text{value} \rightarrow T.\text{value} \end{array}$$

$\checkmark$   
attributes

1) Synthesized

If a parent node is known

Ex:-

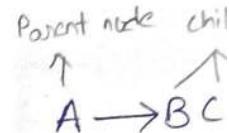

A.value

A.value

A.value

In the above attribute. Bec node B.value

2) Inherited

If a child no siblings nodes attributes

Ex:- B.value =

B.value =

B.value = !

In the above attribute. Bec A.value with si

## Synthesized attributes:-

Parent node - child nodes

$$A \rightarrow BCD$$

If a parent node gets value from child node then that node is known as synthesized attributes.

Ex:-

$$A \cdot \text{value} = B \cdot \text{value}$$

$$A \cdot \text{value} = C \cdot \text{value}$$

$$A \cdot \text{value} = D \cdot \text{value}$$

In the above example, A·value is known as synthesized attribute. Because, A·value is obtained from child node B·value, C·value, D·value.

## Inherited attribute:-

Parent node - child nodes

$$A \rightarrow BCD$$

If a child node gets values from parent nodes (or) it's siblings nodes. then that node is known as Inherited attributes.

$$\text{Ex:- } B \cdot \text{value} = A \cdot \text{value}$$

$$B \cdot \text{value} = C \cdot \text{value}$$

$$B \cdot \text{value} = D \cdot \text{value}$$

In the above example, B·value is known as Inherited attribute. Because, B·value is obtained from parent node A·value with sibling nodes C·value & D·value.

## Evaluation Orders for SDD's

Dependency graph determine the evaluation order of attributes in a parse tree.

Dependency graph:

Consider an example

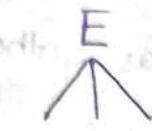

Production Rule

$$E \rightarrow E_1 + T$$

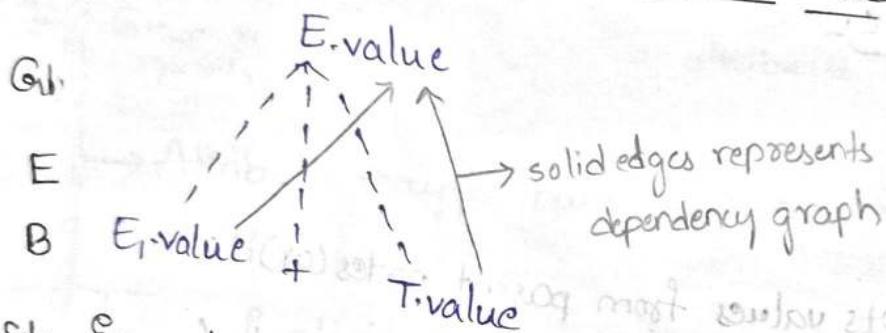

Semantic Rule

$$E.\text{value} \rightarrow E_1.\text{value} + T.\text{value}$$

Parse tree for production rule

Annotated parse tree for semantic Rule

Example:

Given grammar

$$T \rightarrow FT'$$

$$T' \rightarrow *FT_1'$$

$$T_1' \rightarrow \epsilon$$

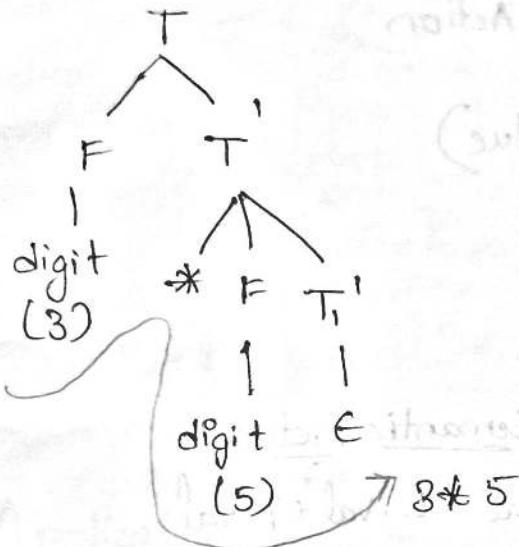

$$F \rightarrow \text{digit}$$

Given Input string:  $3 * 5$ .

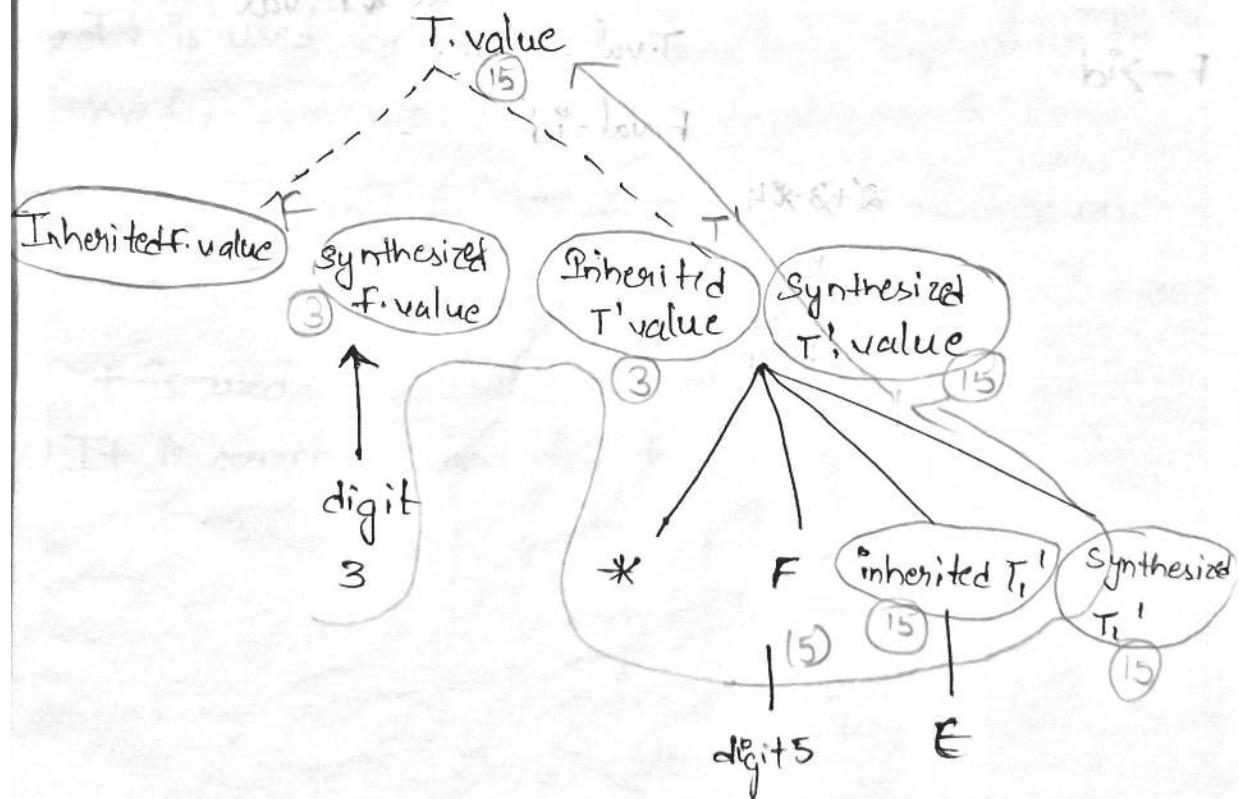

Now find out the Evaluation order of given Input string.  
or given grammar.

Parse tree for given Input string:-

$* 5$

Annotated parse tree for given Input string:-

redu 02/06/2022

## SDT (Syntax Directed Translation)

We

redi

fc

SDT is used for semantic analysis. SDT is basically used to construct the parse tree with grammar and semantic action. So, we can say that

we

$$\text{SDT} = \text{Grammar} + \text{Semantic Action}$$

Q3/10

Car

Ex:-

$$(E = E + T + E.\text{value} + T.\text{value})$$

Ex:-

$$\text{Input} \rightarrow 2+3*4$$

$$\text{output} \rightarrow 14$$

Grammes

$$E \rightarrow E + T \mid T$$

$$T \rightarrow T * F \mid F$$

Gib

$$F \rightarrow \text{id}$$

E

B

Ste

Semantic Action

$$E.\text{val} = E.\text{val} + T.\text{val}$$

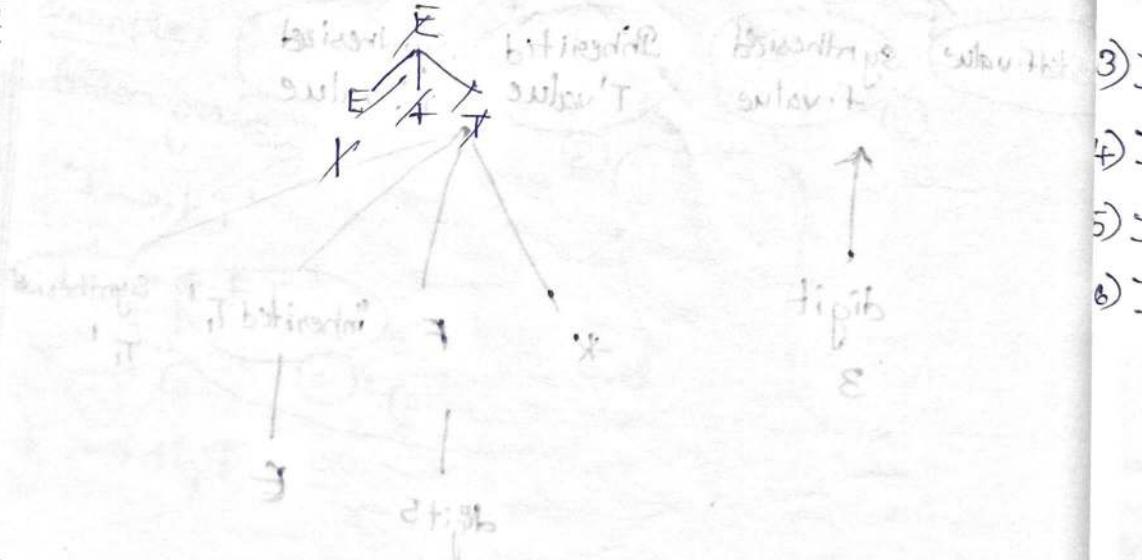

$$E.\text{val} = T.\text{val}$$

$$T.\text{val} = T.\text{val} * F.\text{val}$$

$$T.\text{val} = F.\text{val}$$

$$F.\text{val} = \text{id}$$

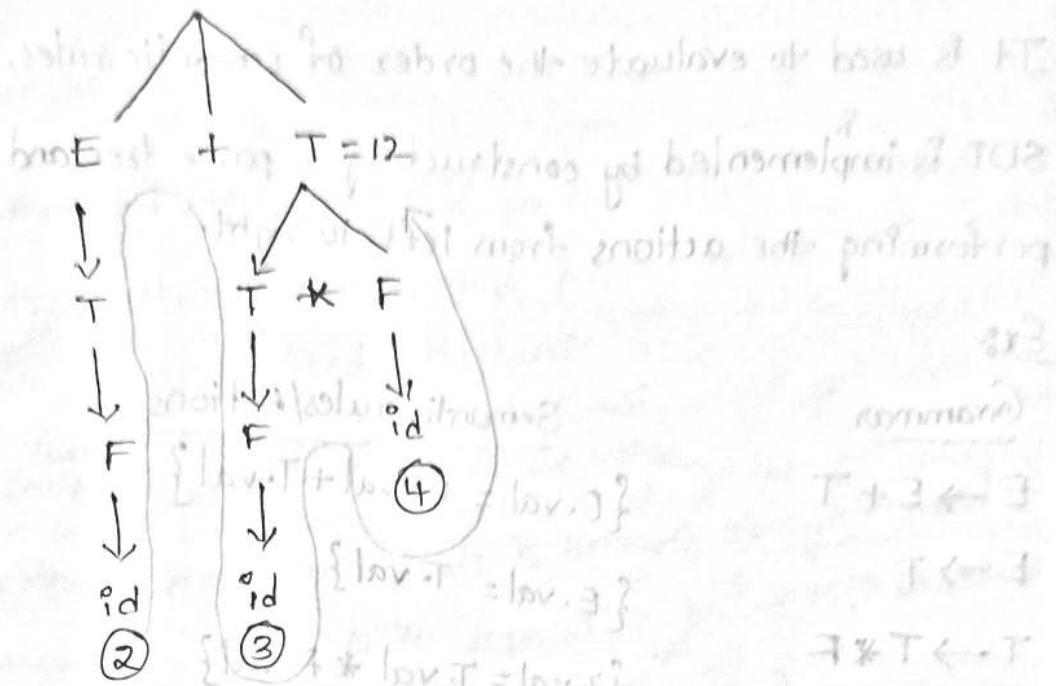

$$2+3*4$$

## Parse tree

$2 + 3 * 4$

$E = 14$

## Applications

- 1) SDT is used for executing arithmetic expressions.
- 2) It is used for conversion from infix expression to prefix expression or postfix expression.
- 3) It is also used for binary to decimal conversion.
- 4) It is used for creating a syntax tree.
- 5) It is used to generate intermediate code.
- 6) It is commonly used for type checking.

red 07/06/2022

## Syntax directed translation schemes

We

SDT = Grammar + Semantic rules.

↳ Implementation

red

It is used to evaluate the order of semantic rules.

+

SDT is implemented by constructing a parse tree and performing the actions from left to right.

Q3/c

Ex:-

Co

Grammar

→  $E \rightarrow E + T$

Semantic rules/Actions

{ $E.\text{val} = E.\text{val} + T.\text{val}$ }

→  $E \rightarrow T$

{ $E.\text{val} = T.\text{val}$ }

→  $T \rightarrow T * F$

{ $T.\text{val} = T.\text{val} * F.\text{val}$ }

→  $T \rightarrow F$

{ $T.\text{val} = F.\text{val}$ }

→  $F \rightarrow \text{num}$

{ $F.\text{val} = \text{num.lexvalue}$ }

Q4

Ex:- Given string

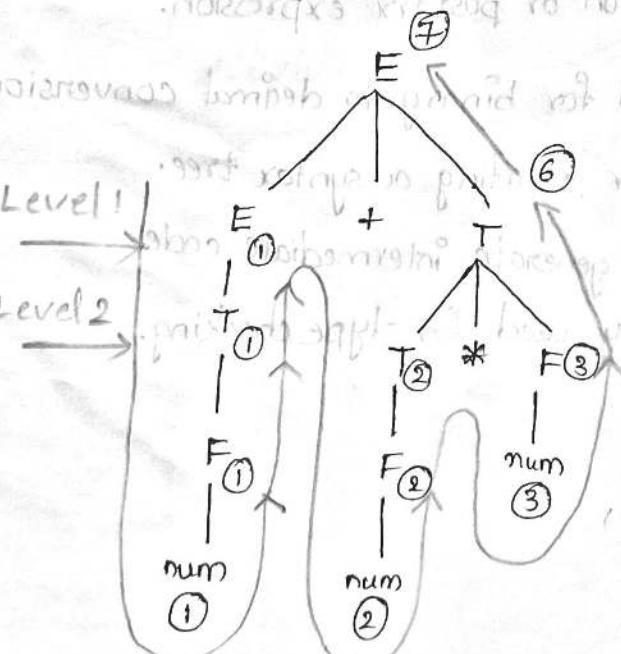

E

1 + 2 \* 3

B

Level 1

Level 2

St

2) Inhi

Pf a

sibling

inheritec

Ex:- A

child

B..vc

c..va

D..val

## Implementing S-attribute and L-attributes

There are 2 types of attributes. They are :-

1) Synthesized attributes

2) Inherited attributes.

1) Synthesized attribute :- If parent attribute depends on children attributes then that parent attribute is known as synthesized attribute.

Ex:- Parent children  $\Rightarrow$  A.val = B.val  
A.val = C.val  
A.val = D.val

In the above example, A is known as synthesized attribute because A is depending on B or C or D with values.

This parent attribute is also known as S-attribute.

2) Inherited attribute :-

If an attribute depends on parent attribute or sibling attributes then that attribute is known as inherited attribute.

Ex:- A  $\rightarrow$  BCD

child  $\rightarrow$  parent or sibling

$$B.val = A.val$$

$$C.val = B.val$$

$$D.val = B.val$$

L-attribute Studictt-1 has attribute-3 position.

Val of an attribute depends on left side synthesized (or) 08/08

Inherited attributes then it is known as L-attribute.

### Ex: Grammer

$$A \rightarrow BCD$$

1) C.val = D.val

2) D.val = B.val

3) C.val = A.val

4) A.val = B.val

- In the above example 2 and 3 statements belongs to L-attributes, remaining statements will not depend on L-attributes.

## Part-2

### Intermediate Code Generator

#### Variants of Syntax Trees

There are 2 types of Syntax trees. They are:-

- 1) Directed Acyclic graphs (DAG) method.
- 2) The value-number Method for constructing DAG.

#### Directed Acyclic graph (DAG) :-

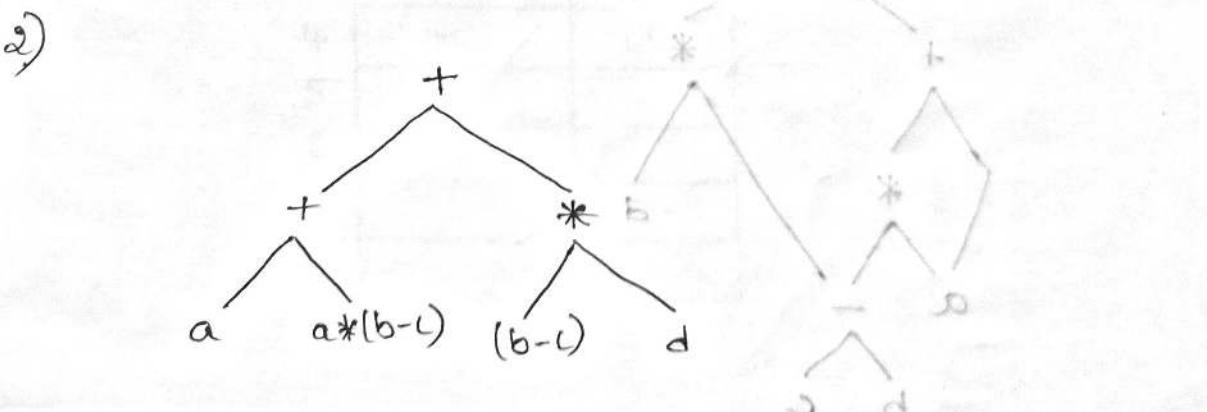

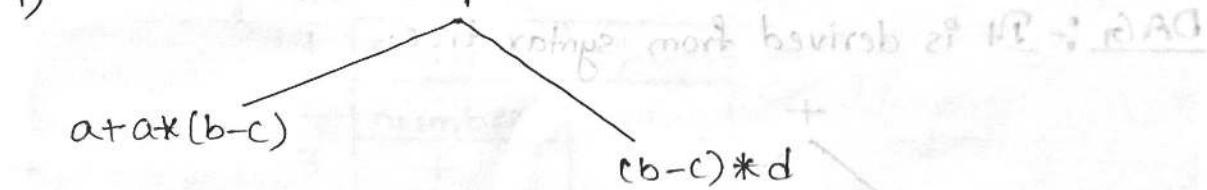

A Directed Acyclic graph identifies the common sub expression in a given expression.

A DAG tree contains operands in the leaves and operators in the interior nodes of the tree.

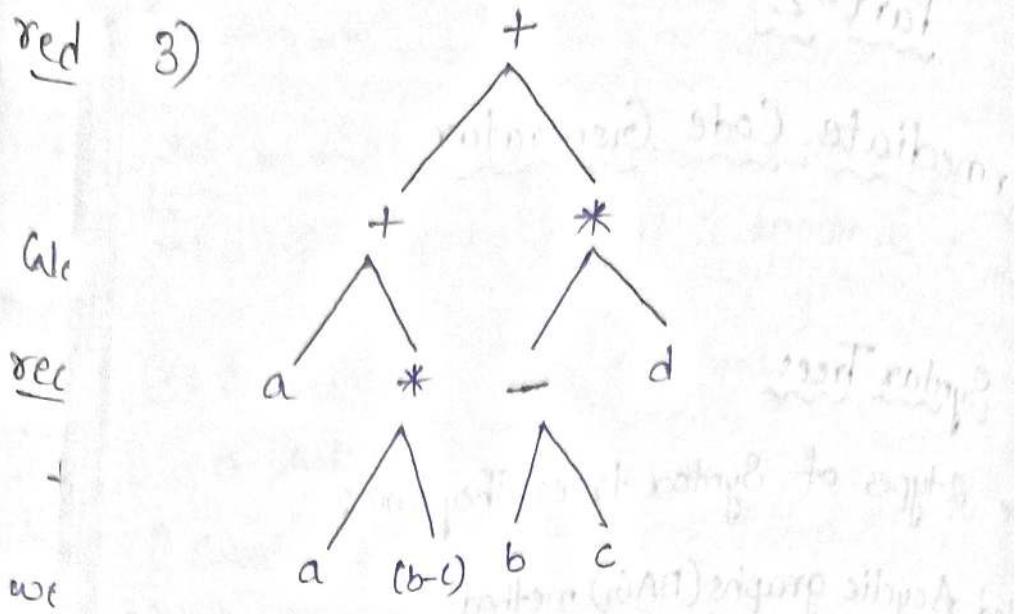

Here a node can have more than one parent.

Ex:-

1) So  $a + a * (b - c) + (b - c) * d$

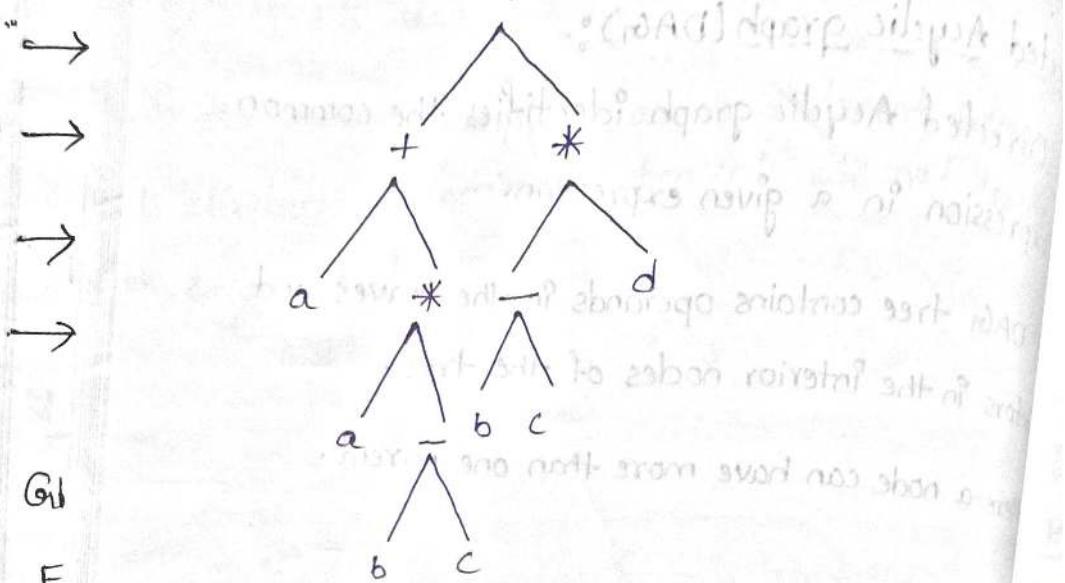

red 3)

23)

C<sub>c</sub>

4)

G<sub>b</sub>

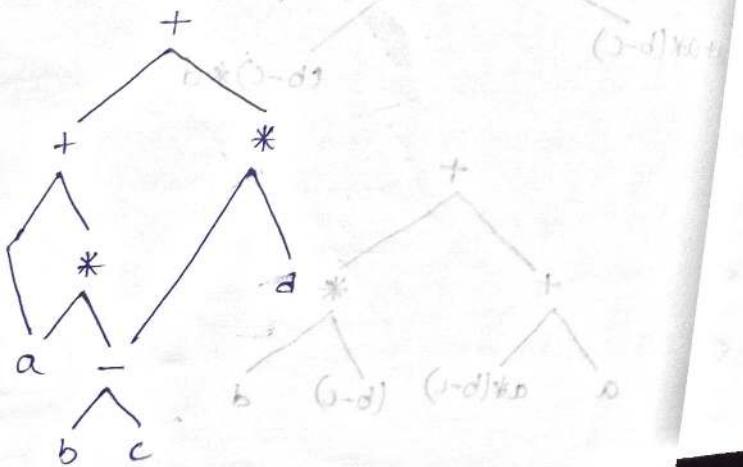

E

B

Let us convert it into DAG.

DAG :- It is derived from syntax tree.

St

Nod

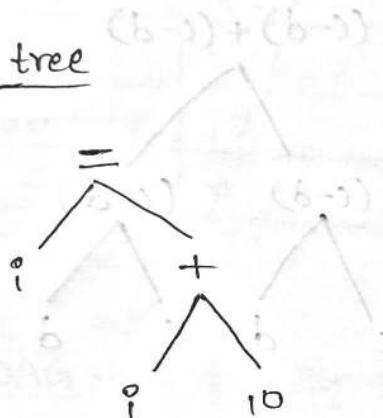

Here node can have more than one parent.

The value number method for constructing DAG :-  
In value number method the nodes of syntax tree (or)  
DAG tree are stored in an array of record.  
Here we may use hash table to store the data of  
syntax tree.

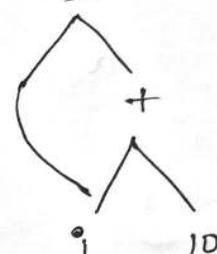

Here array index is known as node value number.

Ex:  $i = i + 10$

Syntax tree

DAG Tree

Nodes of DAG for  $i = i + 10$  is allocated in an array.

array index Meaning

|   |          |     |
|---|----------|-----|
| 1 | identify | $i$ |
| 2 | number   | 10  |
| 3 | +        | 1:2 |
| 4 | =        | 1:3 |
| 5 |          |     |
| 6 |          |     |
| 7 |          |     |
| 8 |          |     |

Ex:  $x = a + b - (c - d) + (e - d)$

edt Syntax tree

(1)

ale

fr

we

2310

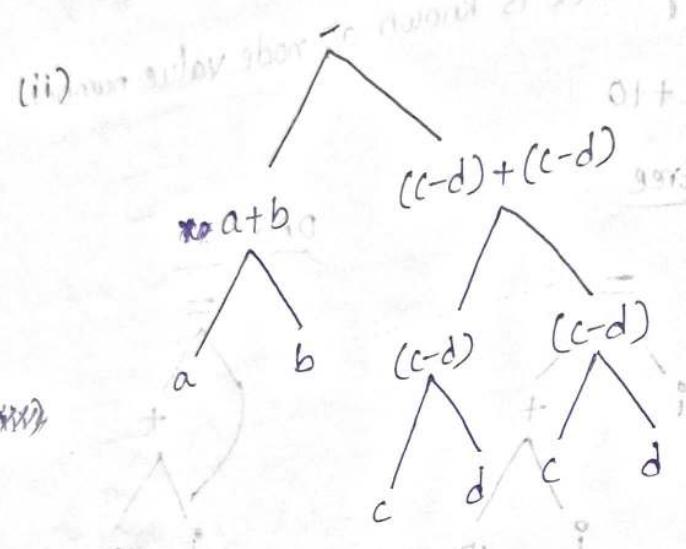

Ca

→

→

→

→

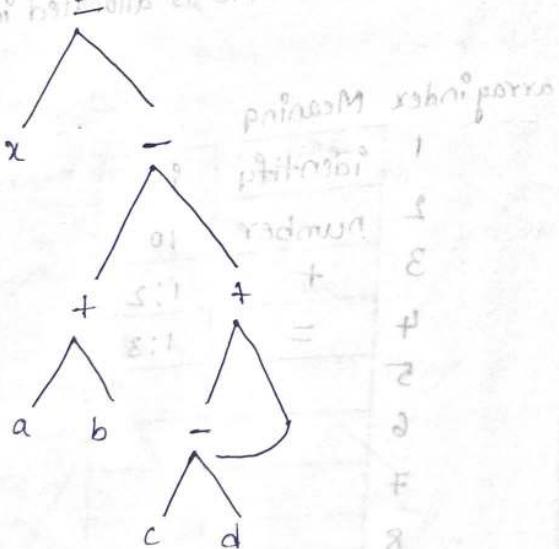

DAG

Gib

E

B

Ste

Nodes of DAG for  $x = a+b - (c-d) + (c-d)$  is allocated in an array.

arrayindex Meaning

|    |          |     |
|----|----------|-----|
| 1  | Identify | c   |
| 2  | Identify | d   |
| 3  | -        | 1:2 |
| 4  | Identify | a   |
| 5  | Identify | b   |
| 6  | +        | 3:3 |
| 7  | +        | 4:5 |
| 8  | -        | 7:6 |
| 9  | Identify | x   |
| 10 | =        | 9:8 |

9/06/2022

Generate the DAG tree for the following expression using stack:-

Step 01 :- Convert the given expression into postfix expression.

Step 02 :- Generate Syntax tree using stack.

Step 03 :- Convert syntax tree into DAG.

Ex:-  $(a+b)*(c-d) + ((c\bar{e}f) * (a\bar{b}))$

Step 01 :-

$$(a\bar{b}) * (c\bar{d}) + ((c\bar{e}\bar{f}) * (a\bar{b}))$$

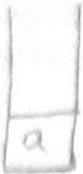

$$\Rightarrow (a\bar{b} \cdot c\bar{d}) * ((c\bar{e}\bar{f}) * (a\bar{b}))$$

$$\Rightarrow (a\bar{b} \cdot c\bar{d}) * ((c\bar{e}\bar{f}) * (a\bar{b})) + (\text{Postfix expression})$$

Step 02 :- Draw syntax using stack.

$$ab+cd-*ef/ab+*+$$

- 1) Push 'a' into stack.

- 2) Push 'b' into stack.

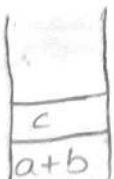

- 3) Push '+' into stack

Perform addition operation  
and draw the syntax tree.

- 4) Push 'c' into stack.

- 5) Push 'd' into stack.

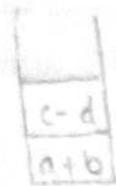

$((a+b)*119)+(c-b)*109$

Perform

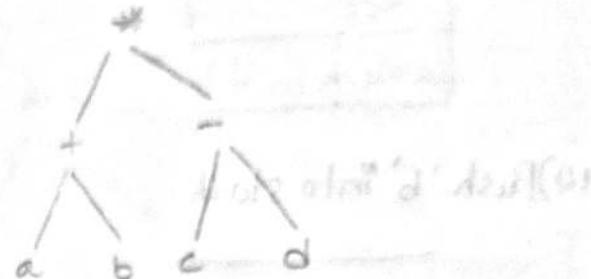

Push '-' into stack.

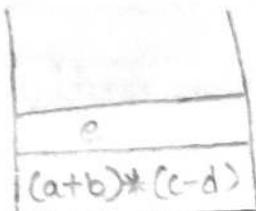

• Note after '-' draw(?)

Push '\*' into stack.

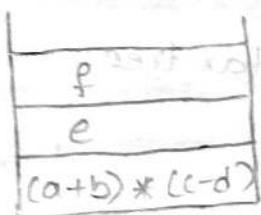

Perform multiplication operation and draw syntax tree.

Push 'e' into stack.

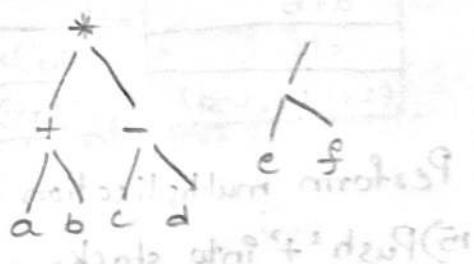

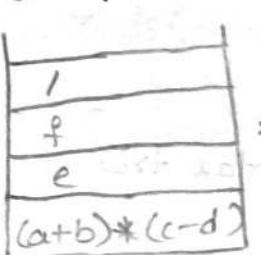

• Note after '+' draw(?)

Push 'f' into stack.

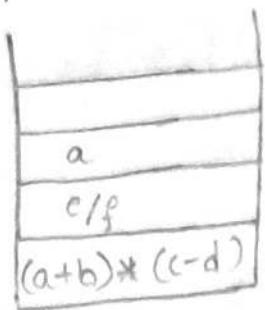

• Note after 'e' draw(?)

Push '/' into stack.

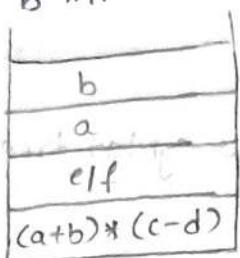

Perform division operation & draw syntax tree.

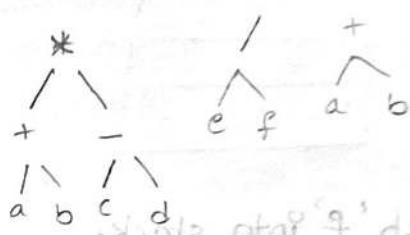

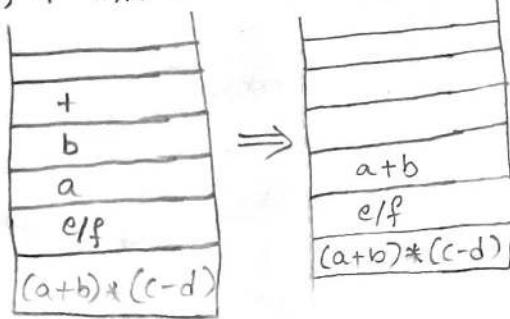

11) Push 'a' into stack.

12) Push 'b' into stack.

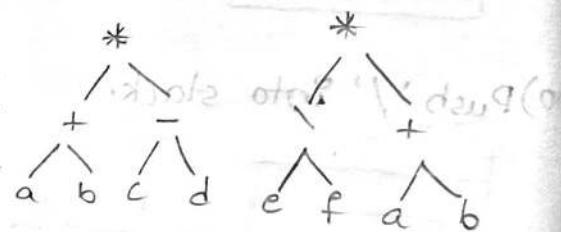

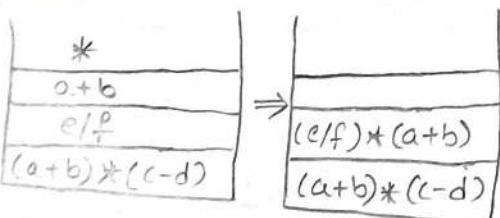

13) Push '+' into stack.

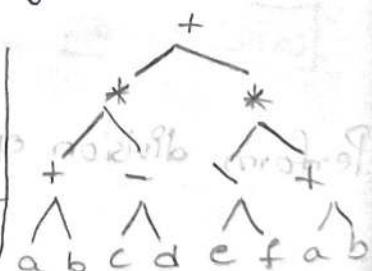

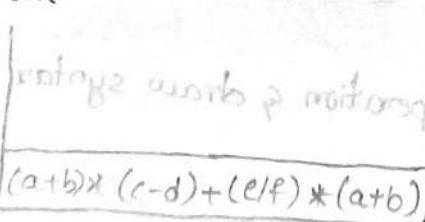

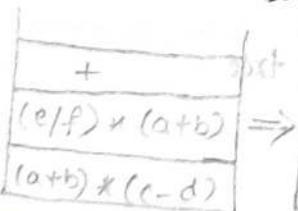

Perform addition operation and draw syntax tree.

14) Push '\*' into stack.

Perform multiplication operation & draw syntax tree.

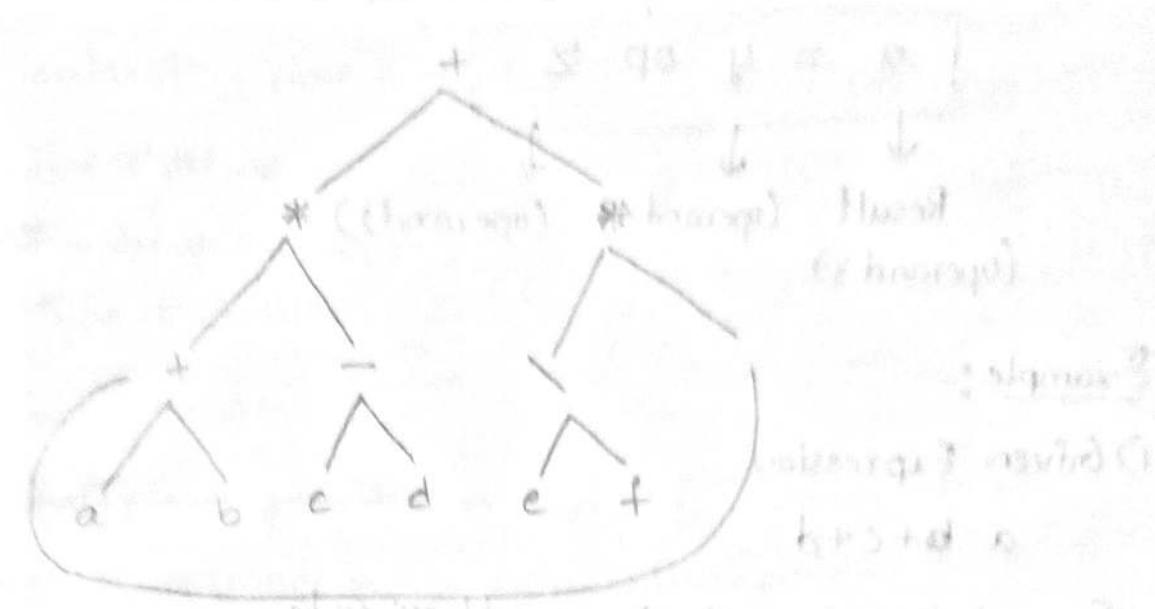

15) Push '+' into stack.

Perform addition operation and draw syntax tree.

Step 03 :-

To draw DAG tree. We have to reduce repeated sub expression.

### Three address code

Three address code is an intermediate code. It is used by optimizing compilers.

In three address code the given expression is broken down into several separate instructions. Now these instructions can be easily translated into machine code.

Each three address code instructions are maximum 3 operands.

It is combination of assignment operator and arithmetic operator.

General form of three address code :-

$$x = y \text{ op } z$$

Result (operand 1) (operand 2)  
(operand 3)

Example :-

1) Given Expression

$$a = b + c + d$$

Convert the above to three address code.

$$\text{temp 1} = b + c$$

$$\text{temp 2} = \text{temp 1} + d$$

$$a = \text{temp 2}$$

∴ This is in the form of three address code.

$$2) a = (-c * b) + (-c * d)$$

Convert into 3 address code.

$$\text{temp 1} = -c$$

$$\text{temp 2} = \text{temp 1} * b$$

$$\text{temp 3} = \text{temp 1} * d$$

$$a = \text{temp 2} + \text{temp 3}$$

## Types and declarations

While evaluating the expression the need of types and declarations play a major role.

- 1) Type checking
- 2) Translation application
- 3) Type expression

### 1) Type checking :-

Before evaluating the expression type checker checks the type of operands in the expression whether to find out it is possible to execute the expression or not.

Ex:-  $a * b$  execution is possible  
int int

$a * b$  execution is not possible.  
int char

### 2) Translation application :-

From the type of the variable it allocates storage space to the operands.

Eg:-  $\text{int } a;$  → It allocates 16 bits of storage space.

$\text{char } a;$  → " " 8 bits " " "

11/06/2022

3) Type Expression:- Type expressions are formed from basic types like int, float, double, char.

Generally, type checking depends on particular language we are using.

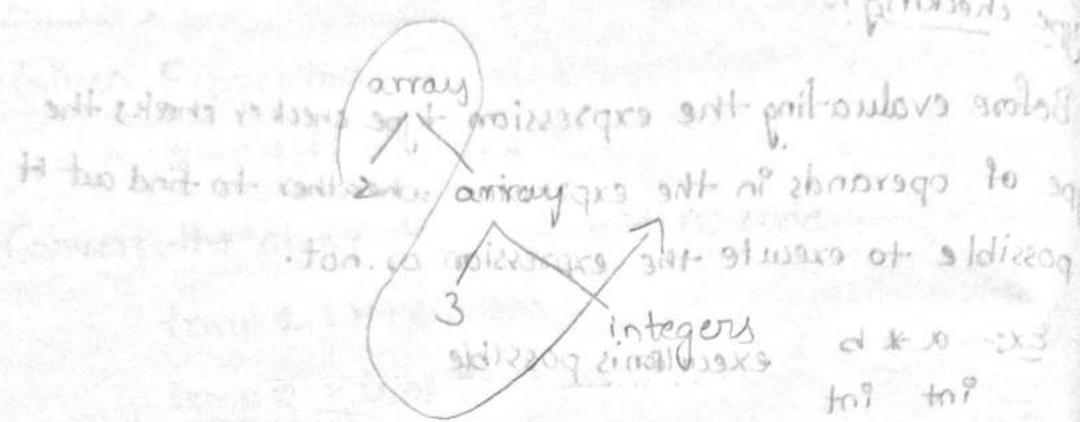

Eg:-  $\text{int}[2][3];$

The above declaration can be read as "array of array of 3 integers each".

The above declaration is written as

array(2, array(3, integers)) in intermediate code.

The type expression of `int[2][3];` in tree structure is shown below:

### Control Flow

Generally we use if statement or if-else statement or while statement or switch case-statement to jump the cursor from one location to another location in the program.

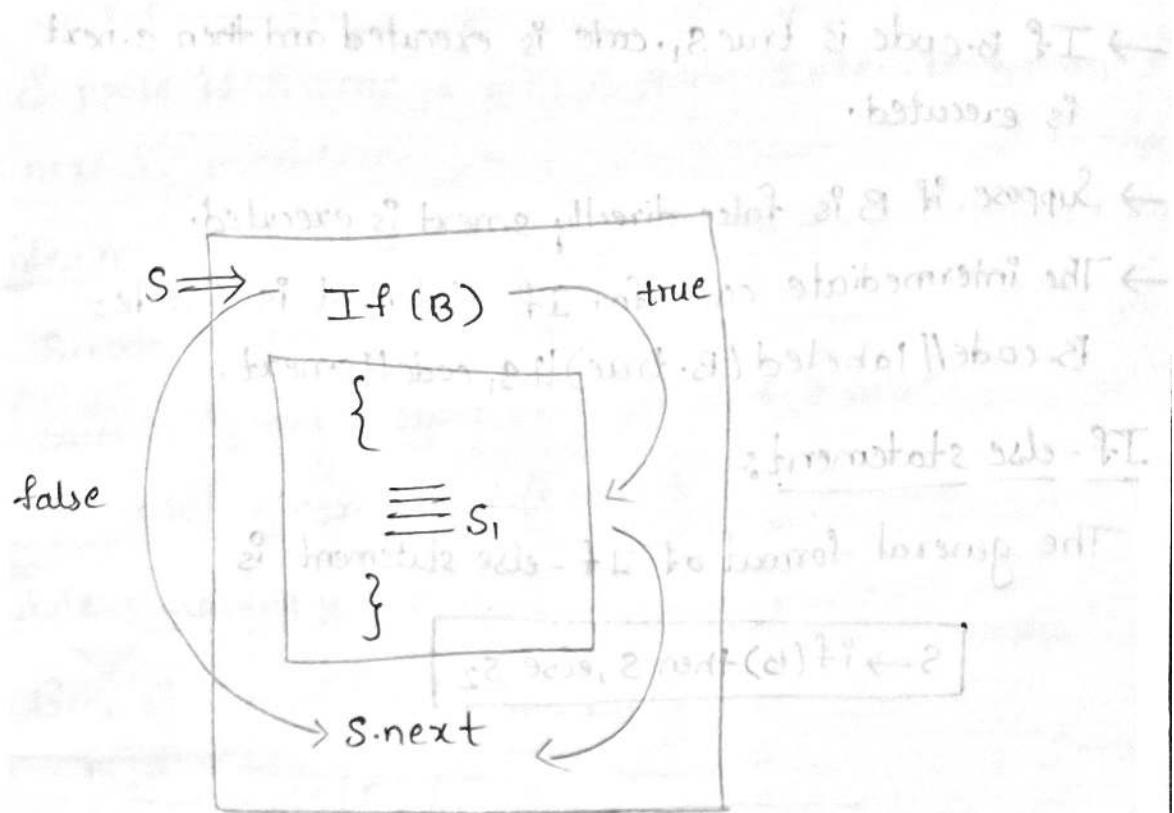

Therefore, these statements are also known as Control Flow statements.

If statement:-

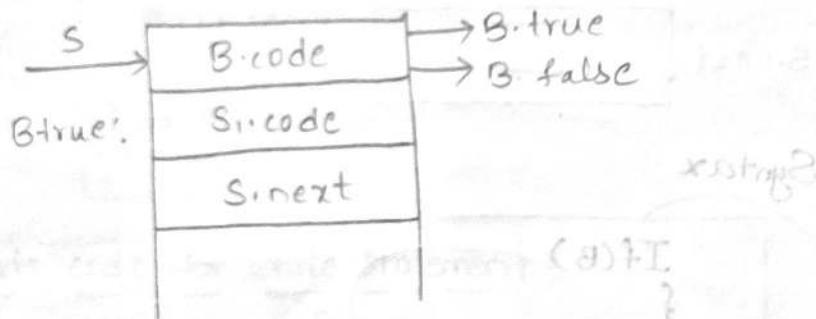

$S \rightarrow \text{if}(B) S_1 \quad S_2$

$\{S_1\} \{S_2\}$

## General format of If statement

## Representation of execution of If statement :-

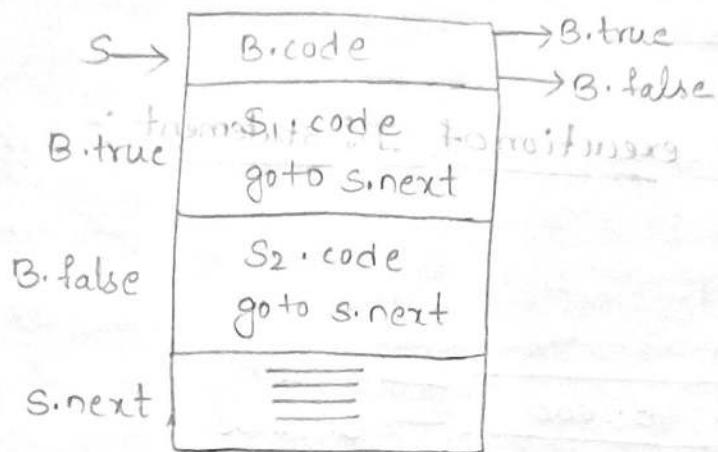

- Here B-code is also known as condition branch.
- If B-code is true s..code is executed and then s.next is executed.
- Suppose if B is false directly s.next is executed.
- The intermediate code for If statement is s.code = B.code // labeled (B.true) || s.code // s.next.

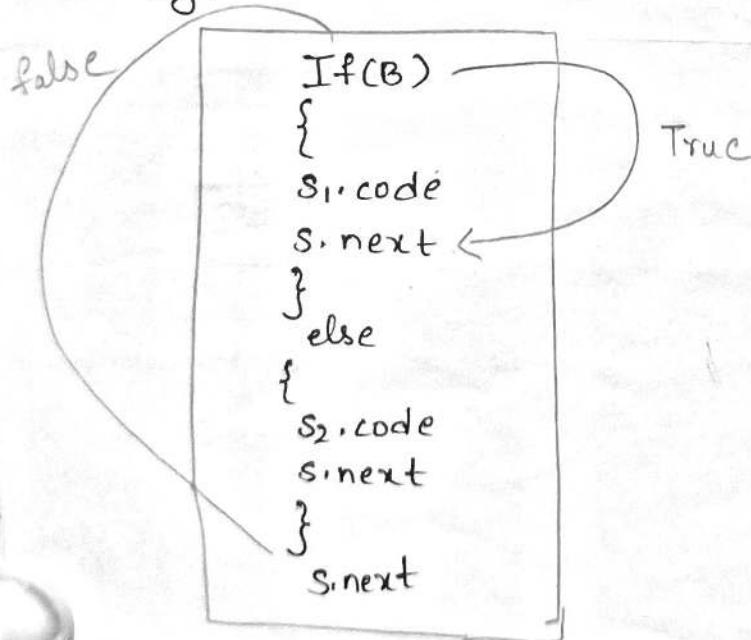

### If-else statement:-

The general format of If-else statement is

$$S \rightarrow \text{if}(B) \text{then } S_1 \text{ else } S_2$$

### Syntax

Here if B-code is true S<sub>1</sub>-code is executed and then S.next is code executed.

Suppose if B-code is false S<sub>2</sub>-code is executed & then S.next is executed.

Intermediate code for If-else statement :-

S.code = B.code // label (B.true) //

S<sub>1</sub>.code // generate (goto S.next) // label (B.false)

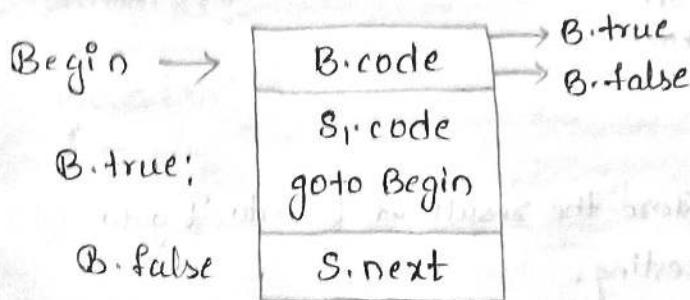

S<sub>2</sub>.code // generate goto (S.next)

While statement :-

General format (Production rule)

$S \rightarrow \text{while}(B)\text{-then } S_1$

If (B.condition) is true S<sub>1</sub>-code is executed this process is continued until B.code is false.

Intermediate code for while statement :-

S.code = B.code // label (B.True) // S<sub>1</sub>.code // generate (goto Begin) // label (B.false) // S.next .

16/06/2022

Switch Case statement:- Generally, we use switch where there are multiple choices & we have to sel. among them In that situation we use switch cas statement.

Syntax of Switch Case statement:

Switch(E)

{

case V<sub>1</sub>; S<sub>1</sub>;

break;

case V<sub>2</sub>; S<sub>2</sub>;

break;

case V<sub>n</sub>; S<sub>n</sub>;

break;

default: S<sub>n</sub>

break;

default:

}

Code to Evaluate E:- Store the result of 'E' into 't' goto testing.

Testing:

If t = V<sub>1</sub>  
goto L<sub>1</sub>

else If t = V<sub>2</sub>  
goto L<sub>2</sub>

if t = V<sub>n-1</sub>  
goto L<sub>n-1</sub>

goto L<sub>n</sub>

next: break;

L<sub>1</sub>: code for S<sub>1</sub>,  
goto next.

L<sub>2</sub>: code for S<sub>2</sub>,  
goto next

L<sub>n-1</sub>: code for S<sub>n-1</sub>  
goto next

L<sub>n</sub>: code for S<sub>n</sub>  
goto next.

06/2022

## Unit-4 Run-Time Environments

### Part-1

#### Run-Time Environments

Generally, memory is allocated in 2 ways.

They are:-

- 1) Static memory allocation
- 2) Dynamic memory allocation.

#### Static memory allocation:

Here memory is allocated only once to the variables in static area.

Memory is deallocated after program is complete.

#### Drawbacks:-

- 1) `int a[5];`

Here, fixed memory cells are allocated. In the above example we can store only 5 values.

Here we can't store more than 5 values.

If we store less than 5 values in the array memory is wasted.

## 2) Dynamic memory allocation

In Dynamic memory allocation memory is allocated the variables during the run-time, that means, memory is allotted only if we give values to the program.

Advantages:- advantages of dynamic memory allocation

- 1) Memory wastage will not be there.

Ex:- node = (struct node\*)malloc (size of (structnode))

malloc and calloc functions are used for dynamic memory allocation.

17/06/2022

## Stack Allocation of Space

In stack LIFO concept is used to store data. The variables in main function and sub function are as active records.

Generally, code of main function is stored in the section 1 of the stack. Only, code of sub program/function is stored in the section 2 of the stack.

When the execution of main function starts the operation pushes all the active records of main function into the section 3 of the stack. Only, when the execution of sub program starts the push operation pushes all the active records of sub function into the section 4 of the stack.

program works with a stack and a stack

Finally, when main program execution completed, pop operation deletes all the active records of section 3 of the stack.

Similarly, when the execution of subprogram is completed pop operation deletes all the active records of section 4.

In this way compiler executes a C program using a stack.

Ex:-

| Quick sort Activation tree                              | Activation Records in Stack                             | Remarks  |
|---|---|--|
| main()<br>{ int n;<br>}                                 | main()<br>{ }<br>int n;                                 | main() is activated.                                   |
| main()<br>readarray()<br>for i = 0 to n<br>do something | main()<br>{ }<br>int n,<br>readarray()<br>{ }<br>int i; | readarray subprogram is activated.                     |
| main()<br>readarray()<br>quicksort()<br>push            | main()<br>{ }<br>int n<br>quicksort()<br>int j          | readarray() is deactivated and quicksort is activated. |

22/06/2022

## Heap allocation

The drawback of stack allocation is it removes the activation records from the memory of its usage is completed. So, retain of activation records is not possible in stack allocation.

in heap

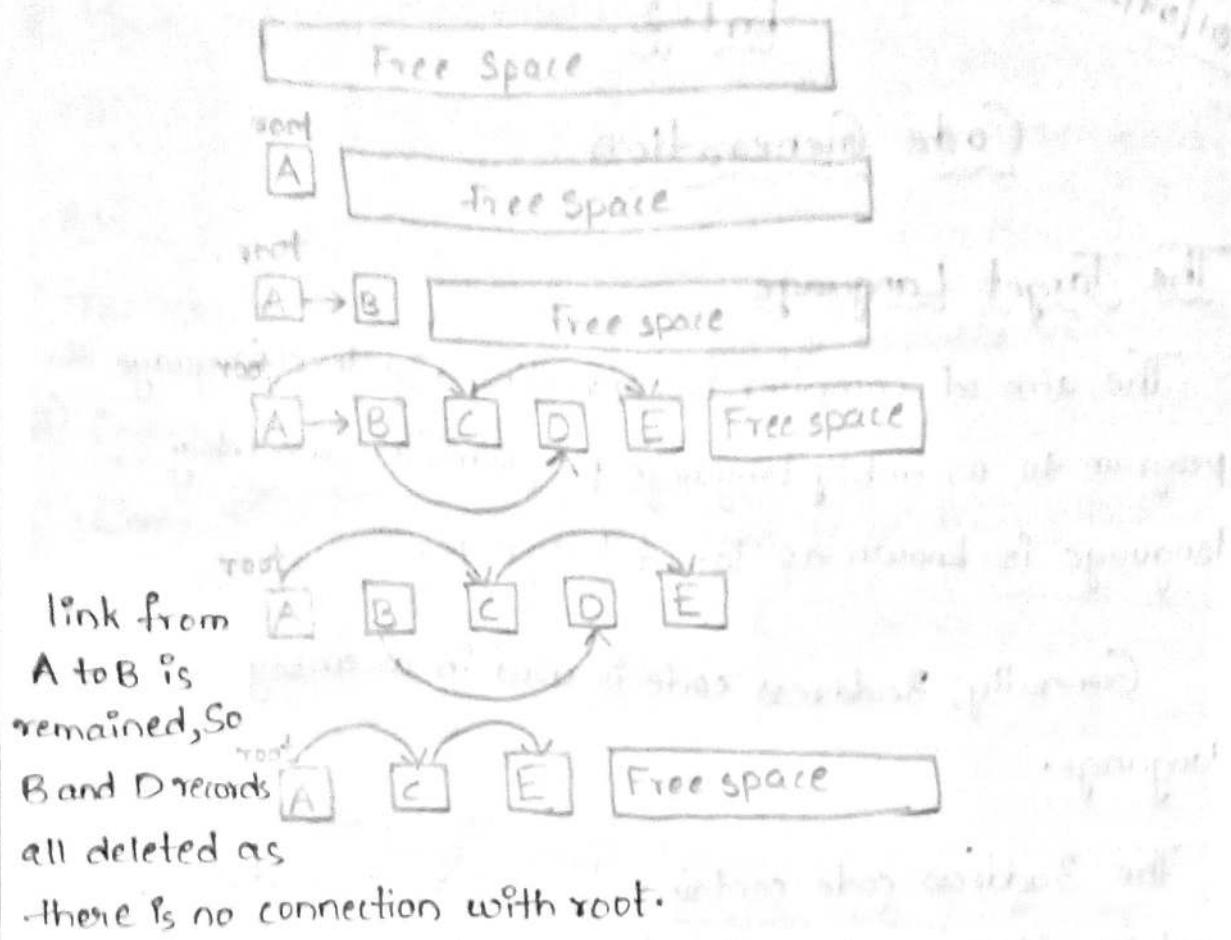

Retain of activation records is possible because activation records are not deleted from the memory even though their usage is completed

in heap allocation.

| Position in activation tree        | Activation records in heap                | Remarks  |
|------------------------------------|---|--|
| ① main() → ② readarray() → ③ qsc() | <pre> main()   readarray()   qsc() </pre> | Retain of activation records<br>readarray() is possible because after readarray(), procedure ends, it is still in the heap, it is not deleted. |

## Introduction to Garbage Collection

Removing unused data from the memory and adding that memory to free space is known as garbage collection.

### Introduction to trace-based Collection

Garbage collector runs continuously to detect unused objects and make memory free whereas trace-based collector runs whenever free space is exhausted or its amount drops below some threshold value, at that time only trace-based collector executes automatically and detects unused objects and makes memory free.

By using Garbage collectors system performance will be reduced whereas system performance increases by using trace-based collector.

01/07/2022

## Part-2

### Code Generation

#### The Target Language

The aim of compiler is converting high level language program to assembly language program. This assembly language is known as Target Language.

Generally, 3 address code is used in assembly language.

The 3 address code contains load, store, computation, and condition, un-condition statement.

##### 1) Load :-

Load is used to move value from variables to registers.  
General format of load is  
`src-reg, dest-reg, address`

Ex:-

`Ld r, x`

Here, the value of variable  $x$  is loaded in register  $r$ .

## 2) Store:-

This instruction moves values from registers to variables.

Ex:- ST  $x, y$

The value of register  $y$  is stored in variable  $x$ .

## 3) Computation statement:-

Computation statements are used to perform addition, subtraction, multiple, division etc.,

General format is

op code destination, src1, src2

Here op code is known as operation code. It may be add (or) sub (or) mul etc.,

In the above format, the values of src1 & src2 are computed & result is stored in destination.

Ex:- Add  $z, x, y$

Add  $r_1, r_2, r_3$

In the above instruction,  $r_2$  data &  $r_3$  data are added & result is stored in  $r_1$ .

#### 4) Un-conditional Jump:-

The general format of unconditional statement is

BR L

BR - Branch

L - Label

In the above instruction, control jumps from current position to the label placed in the program.

#### 5) Conditional Jump:-

The general format is

BR (condition) L

Here, control jumps from one location to another location based on condition checking.

#### Addresses in the Target Code

1) Static Allocation

2) Dynamic allocation.

#### 3) Stack allocation:-

In static, fixed memory is allocated to the variable.

Here, memory cannot be changed.

Ex:- int a[5];

2) Dynamic allocation: here memory is allocated at runtime of the program.

Ex:- stack, heap, linked list etc.

### Stack:-

In stack, activation records are inserted into stack using push operation.

After execution is completed, activation records are deleted from stack using pop operation.

In stack, activation record data is not available after execution of the program, because activation records are deleted from stack after execution.

### Heap:-

In heap, activation records data is available forever because activation records are not deleted even after execution of the program.

### Basic blocks

The basic block is a sequence of consecutive statements which are always executed in sequence of without halt or possibility of branching.

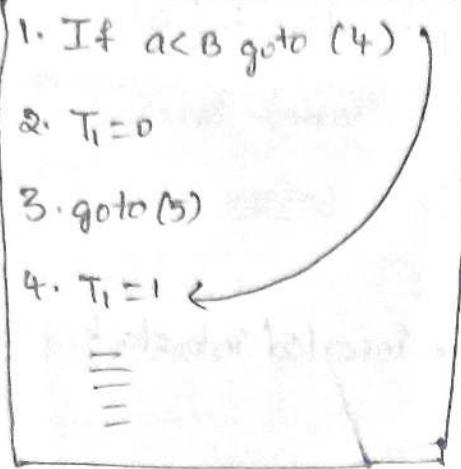

The basic block does not contain jump statements.

Three address code

Ex:-

$$\begin{aligned} t_1 &= b+c \\ t_2 &= t_1+d \\ a &= t_2 \end{aligned}$$

Basic block

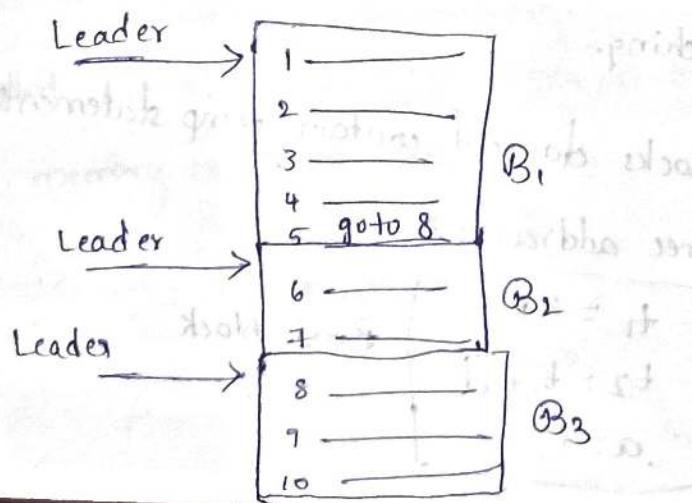

Problem  
Convert

### Rules for partitioning program into blocks

When an intermediate code is generated we can use the following rules to partition the program into basic blocks.

Rules :-

- 1) The first statement is a leader.
- 2) Any target statement of conditional or unconditional statement is a leader.
- 3) Any statement that immediately follows goto statement is a leader.
- 4) The basic block starts with leader statement & ends with the line before the line of next leader statement.

Flow

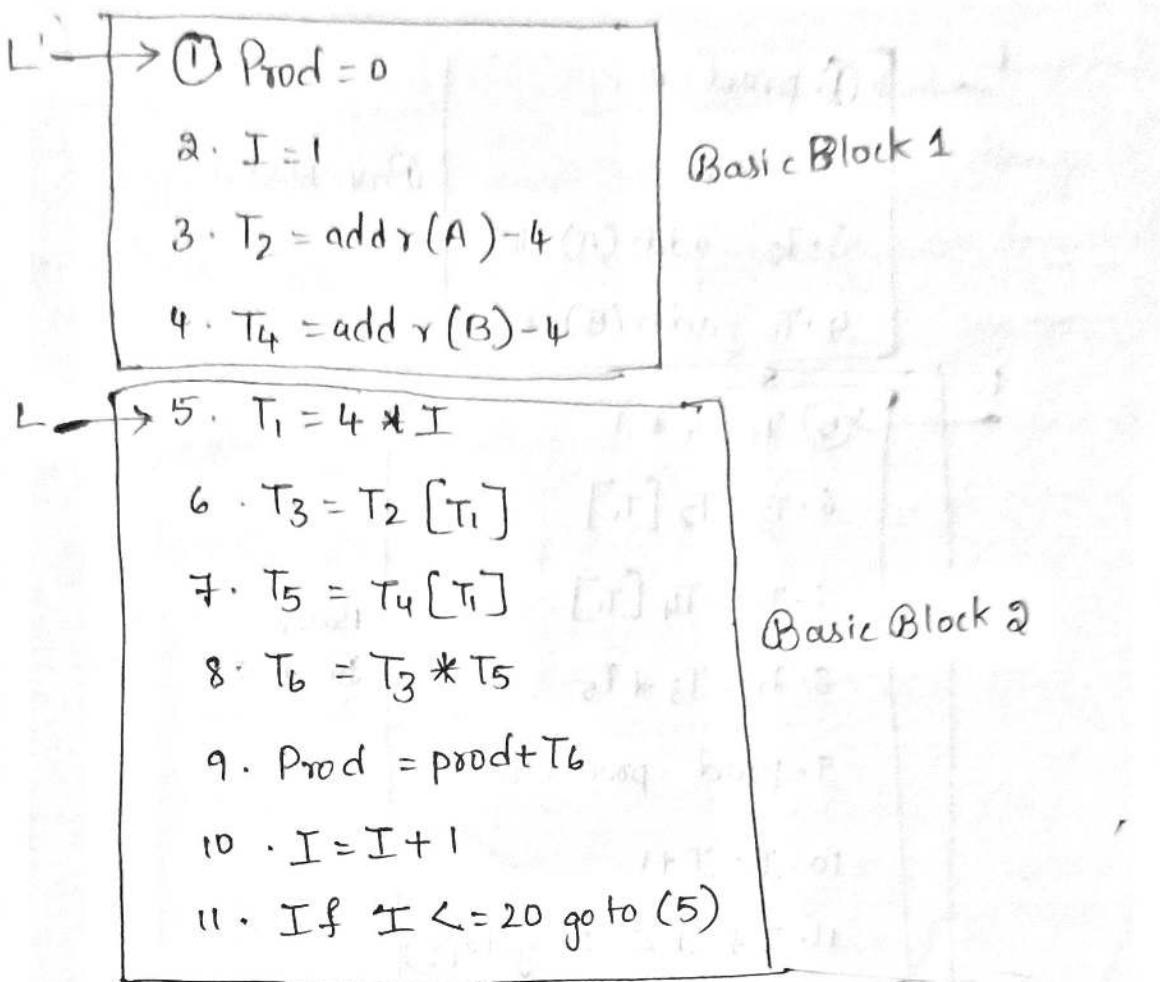

flow  
block

Rules

- 1) Th
- 2) If
- basic
- bloc

## Problem

Convert the three address code into Basic blocks

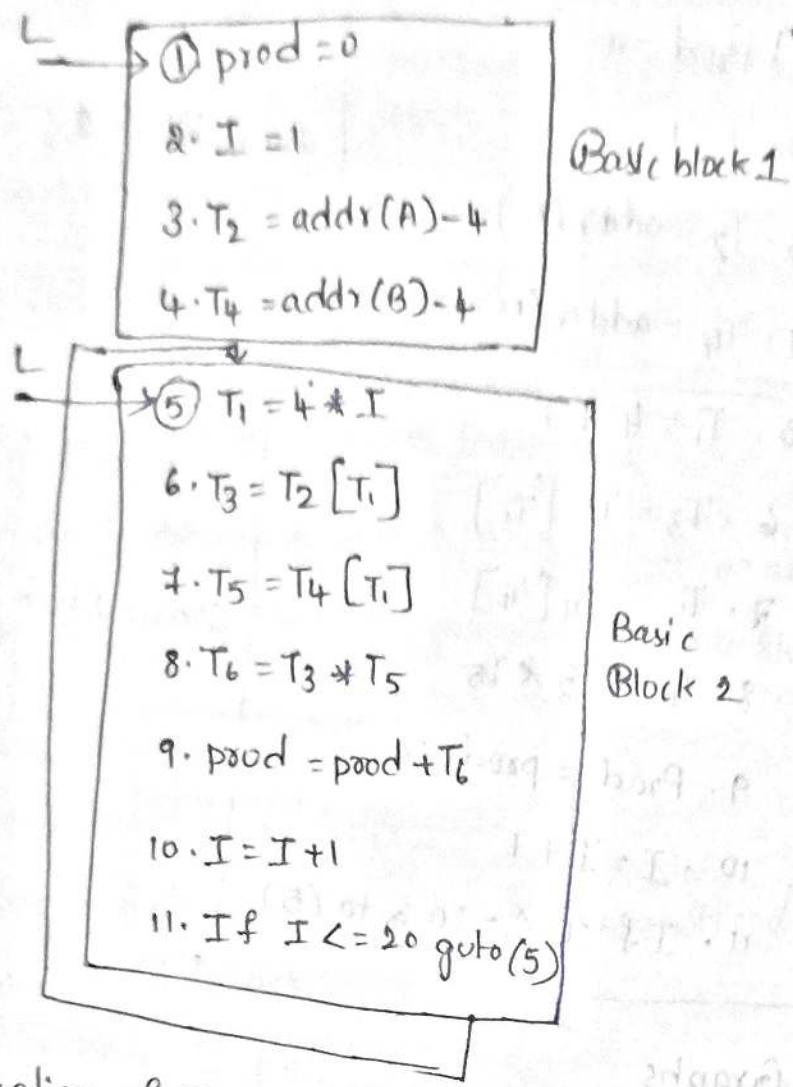

## Flow Graphs

A flowgraph is a directed graph in which the flow of control & information is added to the basic blocks.

### Rules for flow graph:-

- 1) The directed edges are placed b/w basic blocks.
- 2) If Basic block 2 is to be executed immediately after basic block 1, there should be a directed edge from basic block 1 to basic block 2.

Let us convert the above 3-address code into flow graph.

### Optimization of Basic Blocks

Optimization techniques increases the performance of the code by saving memory and execution time.

Optimization code techniques are:-

1. Dead code elimination :- Dead code means the code which never executes is known as dead code.

Ex:- `main()`

{

$x = 10;$  → Dead code  
remove it  
 $y = 20;$   
 $z = 30;$

`main()`

{

$y = 20;$   
 $z = 20;$   
 $p = 2 * y + z$

} optimized code

$$P = 2 * y + z$$

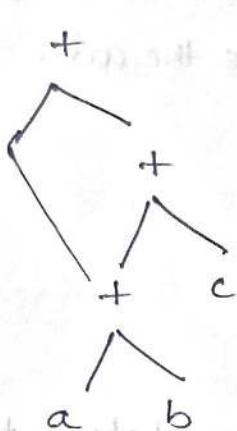

{

## 2) Common Subexpression Elimination:-

By removing Common Subexpression execution speed will be increased memory space is saved.

By using DAG technique we can remove common subexpression.

Ex:-  $x = (a+b) + (a+b) + c$

10/7/2022

## 3) Constant folding:-

If we collaborate constant expressions memory space will increase & execution time increases.

So, by constant folding we can optimize the code.

Ex:-  $x = a * 3 + y \rightarrow$  original code

$x = 6 + y \rightarrow$  optimized code.

#### 4) Copy propagation:-

Copy propagation of two types. They are:-

i) Variable propagation

ii) Constant Propagation.

#### i) Variable propagation & Constant Propagation

If variable (or) constant propagates through a no.of's execution time will be increase and also memory space will also increase.

∴ we should try to eliminate variable propagation or constant propagation to optimize the code.

$$\text{Ex:- } x = y$$

$$z = y + 3$$

$$\underline{z = x + 3}$$

#### 5) Strength Reduction :- (Expensive statement).

We should try to replace expensive statement with cheaper statement to optimize the code.

Ex:- Expensive statement

$$\boxed{x = z * y}$$

→ Cheaper statement

$$\boxed{x = y + y}$$

## A Simple Code Generator

Code generator is used to produce the target code for three address statements. It uses regular registers to store 3 address statements. Here target code is also called as Assembly language code.

| Statement   | Code generated                      | Register description                 |
|-------------|-------------------------------------|--------------------------------------|
| $t = a - b$ | MOV R0, a<br>SUB R0, b<br>STR t, R0 | R0 contains a<br>R0 value store in t |
| $u = a - c$ | MOV R1, a<br>SUB R1, C<br>STR u, R1 | R1 contains a<br>R1 value store in u |

## Peephole Optimization

It is a type of code optimization.

### Objectives:-

- 1) To improve performance.
- 2) To reduce memory size.
- 3) To reduce code size.

### Techniques:-

For this technique

- 1) Redundant Load to store elimination.
- 2) Constant folding.
- 3) Strength Reduction.

### 1) Redundant Load and store elimination

In this technique redundancy is eliminated.

#### Initial code

$$y = x + 5$$

$$t = y$$

$$z = t$$

$$w = z * 3$$

#### Optimized code

$$y = x + 5$$

$$w = y * 3$$

### 2) Constant folding:-

Here the code can be simplified by folding the constant values in the expression.

#### Initial code

$$x = 2 * 3;$$

#### Optimized code

$$x = 6;$$

### 3) Strength Reduction:-

The operators that consume higher execution time are replaced by the operators consuming less execution time.

#### Initial code

$$y = x * 2;$$

#### Optimized Code

$$y = x + x;$$
